10th annual ANTENNA ISSUE

• quads vs yagis 12
• folded-umbrella antenna 38
• broadband 80-meter antennas 44
• two-meter mobile antenna 68
• measuring antenna performance 75

emphasis: quads
Before you invest your hard earned money in a linear amplifier, consider what's inside. That's where the difference in quality is obvious. No lightweight, cheaply built components...In Henry amplifiers you will find only the best quality, heavy duty components. We build our amplifiers to perform at peak level month after month, year after year. Both the 2KD-5 and the 2K-4A will operate full legal power continuous duty on all modes. We offer the amateur the linear amplifier that we would want in our own stations.

At Henry Radio we know how to build only one kind of amplifier...the best!

2KD-5 GENERAL SPECIFICATIONS:
* The 2KD-5 is a 2000 watt PEP input (1200 watt PEP nominal output) RF linear amplifier, covering the 80, 40, 20, and 15 meter amateur bands.
* Two Elmac 3-500Z glass envelope triodes operating in a grounded grid circuit.
* Pi-L plate circuit with a rotary silver plated tank coil for greatest efficiency and maximum attenuation of unwanted harmonics.
* Full legal input in all modes. 2000 watts PEP input for SSB. 1000 watts DC input for CW, RTTY and AM.
* Jumper for 115 or 230 VAC. 3 wire single phase.
* 10.5" high x 15" wide x 17.5" deep
* Price...$945.00

3K-A COMMERCIAL/MILITARY AMPLIFIER*
A high quality linear amplifier designed for commercial and military use. The 3K-A employs two rugged Elmac 3-500Z grounded grid triodes for superior linearity and provides a conservative three kilowatts PEP input on SSB with efficiencies in the range of 60%. This results in PEP output in excess of 2000 watts. It provides a heavy duty power supply capable of furnishing 2000 watts of continuous duty input for either RTTY or CW with 1200 watts output. 3.5-30 MHz.
* Price...$1595.

4K-ULTRA*
Specifically designed for the most demanding commercial and military operation for SSB, CW, FSK or AM. Features general coverage operation from 3.0 to 30 MHz. Using the magnificent new Elmac 8877 grounded grid triodes, vacuum tune and load condensers, and a vacuum antenna relay, the 4K-ULTRA represents the last word in rugged, reliable, linear high power RF amplification. 100 watts drive delivers 4000 watts PEP input.
* Price...$3450.

*Not available for sale to amateurs in the U.S.

Export inquiries are invited. Export models of Amateur units available for 10 meter operation also.
Stalking the Ultimate DX.

Now you can really enjoy the challenge of working that tough to work 2-meter DX. The all new Boomer 3.2\lambda yagi gives 16.2 dBi forward gain. A high efficiency balanced feed system, with integral balun, gives a clear, precise pattern. The trigon reflector reinforces Boomer’s 24 dB front to back ratio. Boomer has that right combination of features which will give you long path DX capability or allow you to participate in tropo, sporadic E, meteor scatter and EME activities.

The Boomer is designed to last with a large diameter round boom for more strength with less wind load. It has a reversible truss support, high strength aluminum mounting plates and all stainless steel hardware.

When you install Boomer, you’ll appreciate our typical attention to detail. You can throw away the hack saw and hand drill. Boomer has a detailed instruction manual, precisely cut elements, plus machined and finished components which need only pliers and screwdriver to assemble.

When you are ready to move up to even higher gain, we have complete stacking kits with everything necessary to assemble two, four and larger yagi arrays. Stalk down to your local dealer (anywhere in the world) for full details on Boomer.

NEW MFJ-981 3 KW Versa Tuner IV

For $199.95 you can run up to 3 KW PEP and match everything from 1.8 thru 30 MHz: coax, balanced lines, random wires. Built-in balun, SWR, dual-range forward and reflected power meter.

The NEW MFJ-981 3 KW Versa Tuner IV lets you run up to 3 KW PEP and match any feedline continuously from 1.8 to 30 MHz: coax, balanced line or random wire. This gives you maximum power transfer to your antenna for solid QSOs and attenuates harmonics to reduce TVI and out-of-band emissions. An accurate meter gives SWR, forward, reflected power in 2 ranges (2000 and 200 watts). A new all metal, low profile cabinet gives you RFI protection, rigid construction, and sleek styling.

The MFJ-982 3 KW Versa Tuner IV has balun, 7 position antenna switch. Matches everything: coax, balanced lines, random wires continuously from 1.8 to 30 MHz.

MFJ-981 is for you. If you already have a SWR/wattmeter, the MFJ-982 is for you.

MFJ-980 3 KW Versa Tuner IV has built-in balun for balanced lines. Matches coax, balanced lines, random wires, 1.8 to 30 MHz.

MFJ-980 is for you. This is MFJ's lowest priced 3 KW Versa Tuner IV.

Whether on or off the air, there's probably no Amateur Radio subject discussed more, scrutinized more carefully, or analyzed more qualitatively than antennas — the engineers analyze, the DX operators scrutinize, and the rest of us simply talk. And with the coming of spring and summer, interest in antennas peaks as Amateurs start working on their antenna systems for the coming DX season. If you have been thinking about updating your station antenna, you may find a useful design in this, our annual antenna issue. If you don't plan to install a new antenna this year, this is a good time to take a close look at your existing system to make sure it's operating up to par. Now that the ravages of winter are over, check all the electrical connections for oxidation, inspect the feedline for damage, and if your system SWR is not as low as it used to be, now's a good time to find out why.

If you look at the record, there have been few important breakthroughs in Amateur antenna design since the delta-loop beam and the quagi, and many readers would argue that both of these antennas are actually extensions of existing antenna theory (quads and Yagis). Many specialized antennas have been developed for military and space communications in recent years, but most have little or no application in Amateur Radio. One example is the log periodic or LP, first designed as a microwave antenna, later as a high-frequency wire beam, and finally, for TV reception. The LP has never been especially popular with Amateurs, probably because we operate on segmented bands and the LP is a broadband device. However, there is renewed interest in the LP for DX work on 80 and 40 meters, and if Amateurs are allocated any new high-frequency bands at WARC 79, it's a sure bet that a good many three-band beams will be replaced by rotatable log periodics.

Unlike other areas of electronics and radio communications, where there have been occasional quantum leaps forward, improvements in basic antenna design have been slow and evolutionary, beginning in 1887 with Hertz' classical center-driven dipole. Marconi's first successful wireless experiments used essentially the same antenna: Two large copper plates excited by a spark gap. To increase the distance of his transmissions, Marconi put up larger and larger quantities of wire. Early Amateurs did the same — because of the low frequencies then in use, the DX performance of a station was proportional to the size and height of the station antenna. In fact, many of the radio engineering textbooks of the early 1900s included a mathematical equation attributed to Marconi which showed that communications distance was directly proportional to the square root of antenna height.

The first advances in gain antennas were the result of experiments by commercial radio companies which wanted to improve the reliability of their overseas service. First came the long wire, the vee, and the rhombic; then the lazy-H, Sterba curtain, and Bruce array, followed closely by the Yagi beam and the 8JK flat-top; W9LZX's cubical quad was introduced a few years later. Each new antenna design was eagerly tested by Amateurs who were trying to improve the performance of their stations.

The perpetual need to improve station performance has become something of a tradition in Amateur Radio, and whether it's the result of ever greater band crowding or the competitive Amateur spirit, I don't know, but it certainly is a fact. Single-sideband provided the needed improvement in the early 1960s, and compact kilowatt linears made their contribution in the late 1960s; that left the antenna system. The fact that there were no antenna breakthroughs did not dilute the compelling urge to enhance station performance — if you couldn't improve basic antenna layout and design, you could certainly increase antenna size, and hence, antenna gain.

As an example of this trend, consider the great interest in phased arrays for 40 and 80 meters, sparked primarily by W1CF's QST articles and his big signal on 75 meters. It wasn't too many years ago that most of us were content with a ground-plane antenna on 7 MHz and a dipole (usually not too high) on 3.5 MHz. In those days some of the more serious 40-meter buffs had two element-vertical arrays, and you might have read in one of the magazines about a few daring souls who had 40-meter Yagi beams, but you almost certainly had never actually see one. In recent years, however, big low-frequency arrays and full-sized beams have become relatively commonplace, and the same rationale for greater antenna height and size has begun to permeate 10, 15, and 20 meters. As the late Sam Harris, W1FZJ, used to say when talking about vhf antennas, "If it lasted through the winter, it wasn't big enough." Based on the large number of antennas which came tumbling down this past winter, perhaps we've hit the practical limit!

Jim Fisk, W1HR
editor-in-chief
Imagine All The Places You Can Tuck ICOM’s Remotable IC-280. (Think small.)

The IC-280 2 meter mobile comes as one radio to be mounted in the normal manner: but, as an option, the diminutive front one third of the radio detaches and mounts by its optional bracket, while the main body tucks neatly away out of sight. Now you can mount your 2 meter radio in pint-sized places that seemed far too cramped before.

Measuring only 2 1/2” h x 7” w x 3 1/2” d, the bantam-sized microprocessor control head fits easily into the dash, console or glove box of even the most compact vehicle. Or if those places are already taken by the rest of your “mobile shack,” the IC-280 head squeezes into leftover nooks and crannies under the dash, overhead, under the seat or even on the steering column.

But don’t be misled by the petite size of this subdivided radio: the IC-280 is jam-packed with the latest state of the art engineering and convenience features. No scaled down technology here!

With the microprocessor in the detachable control head, your IC-280 can store three frequencies of your choice plus the dial, which allows you to select from four frequencies with the front panel switch without taking your eyes off the road. These frequencies are retained in the IC-280’s memory for as long as power is applied to the radio, even when power is turned off at the front panel switch. And if power is completely removed from the radio the ±600 KHz splits are still maintained!

The IC-280 works frequencies in excess of the 2 meter band with ICOM’s outstanding single-knob tuning, so you can listen around the entire band without fooling with three tuning knobs. With steps of 15 KC or 5 KC, the IC-280 puts rapid and effortless frequency change at your fingertips and instantly displays bright, easy to read LED’s.

Available Options:
- Touch Tone pad/microphone combination, which fits the mic plug on the radio face with absolutely no modification
- 15’ unassembled cable kit for long distance remote mounting of the detachable control head
RX noise bridge

Dear HR:

I found Ted Hart's letter in the August 1978, issue of *ham radio* both interesting and informative. I believe Pappot was the first to describe the R-X Noise Bridge (ham radio, January 1973), but he did not reference the source for the original, resistance-only noise bridge which he improved.

Hart's design, which is marketed as the Model TE 702, is technically interesting but would have an awkward capacity readout range if modified as indicated. Using the resistance values he suggested, calling the fixed and variable capacitors \( C_f \) and \( C_v \), and letting \( X \) represent the resistance from the pot wiper to the upper corner of the bridge, the conditions for balance become:

\[
R_u = \frac{51(100 - X)}{X}
\]

\[
C_u = \frac{X \cdot C_v}{100 - X} - C_f
\]

where \( R_u \) and \( C_u \) are, respectively, the parallel resistance and capacitance of the unknown impedance. As Mr. Hart stated, the resistance range is zero to infinity. Furthermore, with a linear taper pot, the low end of the resistance scale would be spread out and the upper end compressed. For many applications, that would be more desirable than the linear and finite range of the Pappot design.

Conversely, the reactance or capacitance range of Hart's proposed reactance bridge would be awkward or unusable. Note that the estimated value of the unknown capacitance is affected both by the setting of the 100-ohm pot and the variable capacitor. The effective capacitance range is thus dependent upon the resistance measured. Suppose, for instance, that \( C_v \) is a standard broadcast variable with a range 20-365 pF. With \( C_f \) a 180 pF capacitor, the range for capacitance balance with \( R_u = 51 \) ohms would be \(-160 \) pF \( \leq C_u \leq 185 \) pF, which is similar to Pappot's R-X bridge as modified by Gehrze (ham radio, March 1975). But suppose \( R_u \) were 5 ohms. Because of the interaction between pot setting and reactance balance, the capacitance range would now be \( 20 \) pF \( \leq C_u \leq 3470 \) pF. One could not even measure a pure resistance! Similarly, with \( R_u \) equal to 250 ohms, the capacitance range becomes \(-176 \) pF \( \leq C_u \leq -107 \) pF and again does not include a purely resistive impedance. Of course, other values could be chosen for the capacitors, but the effect described above would still cause the reactance range to be severely distorted for \( R_u \) values away from 50 ohms.

Mr. Hart also makes the point that his model TE 702 works to over 250 MHz and that the reactance measuring version thereof would yield "a lot more accuracy — over a wider frequency range." It is well known that, with careful design, resistance-only noise bridges can be made to work well up into the vhf range. Adding the fixed and variable capacitors, however, severely reduces the upper frequency limit. The R-X noise bridge Doting and I described works accurately to 30 MHz, and data to substantiate this claim have been published (ham radio, February 1977). The two commercial R-X noise bridges claim upper frequency limits of 100 MHz. However the manual for one of these units suggests it may require recalibration for use at the higher frequencies; neither makes any claim for accuracy.

Quite independently of how the transformer may be wound, the upper frequency range of the R-X bridge is limited by residual errors in the bridge components themselves. The pot has stray capacitance to ground which changes with the pot setting, and the interconnection wires have reactances which cannot be ignored; most important of all, the variable capacitor has residual series inductance. 250 MHz is well above the series resonant frequency of any reasonable-size variable capacitor. Severe resistance and reactance measurement errors would start to appear well below the resonant frequency. These constraints are recognized by commercial equipment designers; where accuracy is required in vhf impedance-measuring equipment, bridge techniques using discrete components are typically abandoned.

I congratulate Mr. Hart for his invention, the Antenna Noise Bridge. The R-X Noise Bridge pioneered by Pappot was certainly inspired by this invention. Refinements to the Pappot unit which allow calibration and compensation without access to lab standards make the R-X bridge a very useful device for accurate measurements in the high-frequency range.

Orange, California
Digital Frequency Control*
...a Kenwood innovation for maximum HF operating enjoyment!

Kenwood's TS-180S with DFC is an all solid-state HF transceiver designed for the DXer, the contest operator, and all other Amateurs who enjoy the 160 through 10-meter bands. The following features prove beyond doubt that the TS-180S is the classiest rig available!

- Digital Frequency Control (DFC), including four memories and manual scanning. Memories are usable in transmit and/or receive modes. Memory-shift paddle switches allow any of the memory frequencies to be tuned in 20-Hz steps up or down, slow or fast, with recall of the original stored frequency. It's almost like having four remote VFOs!
- All solid state -- including the final. No dipping or loading. Just dial up the frequency, peak the drive, and operate!
- High power: 200 W PEP, 160 W PE on 160-15 meters; and 160 W PEP, 140 W DC on 10 meters (entire band provided). Also covers more than 50 kHz above and below each band (MARS, WARC, etc.), and receives WWV on 10 MHz.
- Improved dynamic range.
- Adaptable to all three proposed (WARC) bands.
- Single-conversion system with highly advanced PLL circuit using only one crystal with improved stability and spurious characteristics.
- Built-in microprocessor controlled large digital display. Shows actual VFO frequency and difference between VFO and "MI" memory frequency. Blinking decimal points indicate "out of band." Monoscale dial, too.
- IF shift...Kenwood's famous passband tuning that reduces QRM.
- Selectable wide and narrow CW bandwidth on receive (500 Hz CW filter is optional).
- Automatic selection of upper and lower side band (SSB NORM/ SSB REV switch).
- Tunable noise blanker (adjustable noise sampling frequency).
- RF AGC ("RGC"), which activates automatically to prevent overload from strong, local signals.
- AGC (selectable fast/slow/off).
- Dual RIT (VFO and memory/15).
- Three operating modes: SSB, CW, and FSK.
- Improved RF speech processor.
- Dual SSB filter (optional), with very steep shape factor to reduce out-of-passband noise on receive and to improve operation of RF speech processor on transmit.
- 6.8 VDC operation.
- Also available is the TS-180S without DFC, which still shows VFO frequency and difference between VFO and "hold" frequencies on the digital display.

All of these advanced features can be yours...and at an attractive price! Visit your local Authorized Kenwood Dealer and inquire about the exciting TS-180S with DFC!

Still available... Kenwood's TS-820S HF transceiver.

KENWOOD

TRIO-KENWOOD COMMUNICATIONS INC.
1111 WEST WALNUT/COMPTON, CA 90220
"RESTRUCTURING," DOCKET 20282, was terminated by an FCC order released late March. The Commissioners left the door open for further action on the unresolved portions of the Docket. Noting that previous Report and Orders on 20282 had tightened up licensing procedures, but expanded Novice and Technician privileges, the Commission reaffirmed its support for some form of no-code entry level "Communicator Class" license despite its rejection by the Amateur community when proposed four years ago.

"We Hope To Revisit this matter later this year in a new Rule Making proceeding," the Commission continued, noting that Amateur Radio had grown by almost 50 per cent (much of the growth in the CB bands) in the last four years, so Amateur attitudes toward "no-code" may have changed. Continued Commission endorsement for "no-code" is well evidenced by their inclusion of relaxed code requirements in the proposals for WARC.

The Proposal To Base Power Limits on output measurements is also still high in Commission interest. However, that subject is also being shelved for the time being while encouraging "Amateurs, in the interim, to develop and disseminate data which could be used as a basis for a workable and state-of-the-art measurement technique."

431-433 MHz WILL Remain "off-limits" to ATV repeaters, the FCC decided at another March meeting. Responding to two Petitions for Reconsideration on Docket 21033, the Commissioners noted that protection for weak signal and satellite operation was appropriate, but ATV repeater operators would always have the option of requesting a waiver. If the operator could establish a need for repeater operation in the protected segment, while showing his operation would not interfere with weak signal work there, such a request for waiver would be granted.

EFFECTS OF CB-ANTENNA RADIATION on the bodies of nearby people is being investigated by the Department of Health, Education and Welfare. The first study, published in a 24-page booklet titled "Measurement of Electromagnetic Fields in Close Proximity of CB Antennas," discusses bumper, trunk lid and rooftop-mounted mobile antennas as well as those on hand-held units. Near field radiation distribution of each type is presented graphically, in an attempt to determine what hazard, if any, radiation presents.

The Study Concludes: "The health implications (of CB-antenna radiation) are not clear at this time. The Bureau of Radiological Health is continuing to investigate this matter." HEW is obviously quite concerned with the effects of RF on the population, and with Amateurs running 200 times the power of CBers on frequencies from 1.8 MHz through millimeter wavelengths, our operations are sure to come under careful scrutiny as well — if they haven’t already.

A 900-MHZ AMATEUR BAND will be enjoyed by Canadian Amateurs sometime later this year, possibly as early as this summer. An announcement by the Department of Communications of the reassignment of 420-430 MHz to another service is considered imminent, and at the same time the granting of 902-928 to the Amateur Service on a shared basis should also be announced.

The Movement of that as yet unspecified "other service" to the presently Amateur 420-430 MHz slot is expected to take place rather quickly. When Canadian Amateurs will be permitted into their new frequencies is less certain.

INTERNATIONAL SUPPORT for new Amateur HF bands at 10, 18, or 24 MHz seems to be building, with formal submissions supporting one or more of the new slots now confirmed from all three ITU regions. Don’t be in too much of a hurry to swap off your present five or six band radios, however. Even if the WARC does authorize new bands for the Amateur Service next summer, it will likely be a number of years before present users can be moved out and Amateurs will be permitted to move in.

"UOSAT" — THE UNIVERSITY OF SURREY SATELLITE — will include a voice synthesizer to provide telemetry transmissions in plain English, a 4,000 character datascore capability, and a slow-scan TV camera for live cloud-cover pictures. Educators who’ve heard about the sophisticated bird are reported very enthused about its classroom possibilities.

PROHIBITION OF RADIO TRANSMISSIONS in residential areas is being considered by the Oregon State Senate. Senate Bill 423, sponsored by Senator Ted Hallock of Portland, proposes sharply restricting all electromagnetic emissions in residential areas.

In Testimony Favoring the bill Merrie Buel, government affairs coordinator for the Oregon Environmental Council, said that medical studies "have found that persons living next to electromagnetic sources often experience serious health effects, including rashes, headaches, dizziness, and tingling sensations." She testified that experts and transmission lines as well as radio and TV transmitters would be curtailed under the bill’s provisions, though Senator Hallock and members of the Senate Committee on Environment and Energy have been discussing removing transmission lines from its coverage.

FIRST WORKED ALL CONTINENTS ON 2 meters was completed January 31 by GW4COT, when he succeeded in working VK5NC via moonbounce at 1132Z.

A New 6-Meter DX Record of 12,059 miles was set in early March when LUBAHW and LH9TG made contact at 0000Z. The same evening several VK4s worked W9TMW/KL7, while ZB2BL heard the Brazilian beacons but was unable to make himself heard through JA/LU QRM.

The same summer advanced QRP techniques were used by the W6RAZ team to make positive operation at 1.8 MHz possible. The team continued operations using an AWA-700, S1950 transceiver and a hand -held transceiver. Many improvements were made to increase performance, and the team was able to make contact with operators in several countries. The W6RAZ team continued to make positive contact with operators throughout the summer, and the team was able to operate for several hours per day. The team continued to improve their techniques and equipment throughout the summer, and the team was able to make contact with operators in several countries. The team continued to operate until the end of the summer, and the team was able to make contact with operators in several countries. The team continued to improve their techniques and equipment throughout the summer, and the team was able to make contact with operators in several countries.
OMNI HAS IT ALL. All the advantages and capabilities, all the new conveniences and new levels of performance you need, whatever your HF operating specialty. All built-in, ready to use.

ALL SOLID-STATE. All the advantages of total solid-state from the pioneer of HF solid-state technology. Reliable, cool, stable — from receiver front-end to transmitter final.

ALL HF BANDS. From 160 through 10 meters (and all the crystals) plus convertible 10 MHz and "AUX" band positions for possible future needs.

ALL BROADBAND. Band changing without tuneup — without danger to the final amp.

ALL READOUTS. Choose OMNI-A for analog dial (1 kHz markings) or OMNI-D for six 0.43" LED digits (100 Hz readability.)

ALL VOX AND PTT FACILITIES built-in; 3 VOX controls plus PTT control at front and rear jacks for external PTT switch.

ALL SQUELCH NEEDS for tuning and monitoring are built-in.

ALL MODE SWITCH puts all filters to work in any mode.

ALL VERSATILE OFFSET TUNING; dual ranges, ±5 kHz range for off-frequency DX or ±0.5 kHz range for fine tuning.

ALL SENSITIVE RECEIVER; from 2 µV on 160 m to 0.3 µV on 10 m (10 dB S+N/N) for ideal balance between dynamic range and sensitivity.

ALL OVERLOADSHandled: dynamic range typically exceeds 90 dB and PIN diode switched 18 dB attenuator also included for extra overload protection.

ALL LINEAR/ANTENNA BANDSWITCHING FROM FRONT PANEL: auxiliary bandswitch terminals on back panel for external relays or circuits are controlled simultaneously by the OMNI bandswitch.

ALL INTERFACE JACKS FOR PHONE PATCH; access to speaker and microphone signals.

ALL-LEVEL ADJUSTABLE ALC: set output from low power to full, retain low distortion at desired drive to power amp.

ALL SIDE TONE ADJUSTMENTS; pitch and volume.

ALL-POWERFUL, ALL-WARRANTED FINAL AMPLIFIER. 200 watts input to final. Proven design with full warranty for first year and pro-rata warranty for additional 5 years.

ALL 100% DUTY CYCLE. For RTTY, SSTV or sustained hard usage.

ALL-MODE POWER: basic 12 VDC for easy mobile use, external supplies for 117/220 VAC operation.

ALL FRONT PANEL MICROPHONE AND PHONE JACKS. Convenient.

PLUS ALL THE OTHER HANDY BUILT-INS: "Timed" 25 kHz crystal calibrator in OMNI-A with automatic 5-10 sec. "on" time for easy 2-hand dial skirt adjustment . . . Zero-Beat switch for placing your signal exactly on CW listening frequencies . . . SWR bridge switches "S" meter to read SWR each time you transmit for continuous antenna monitoring . . . Separate receive antenna capability . . . Dual speakers for greater sound at lower distortion . . . Plug-in circuit boards for fast, easy field service.

ALL-FUNCTIONAL STYLING. "Clamshell" aluminum case clad in textured black vinyl with complementary nonreflective warm dark metal front panel and extruded aluminum bezel and bail. Convenient controls. Complete shielding. And easier-to-use size: 5¼"h x 4¼"w x 14"d.

quads vs yagis revisited

The author attacks an old question in a new way by actually measuring the relative gain of high-frequency quads and Yagis.

Which is the better antenna — a cubical quad or a Yagi? That question has aroused Radio Amateurs’ emotions for more than thirty years now, and remains controversial in spite of the great volume of published research and analysis.

It has been a decade since Jim Lindsay published his classic work on quads and Yagis, presenting both theoretical and empirical data to support his conclusion that the quad was in many ways the better antenna. He concluded that a quad of any length would outperform a similar size Yagi by 2 dB in forward gain. Basing his findings on model quads and Yagis operating at 440 MHz, Dr. Lindsay said that it was necessary for the Yagi to have 1.8 times the boom length of a quad to equal its forward gain.

At the time of its publication, Lindsay’s study seemed conclusive, but in the years since the issue has refused to die. The question has now been subjected to computer modeling, which produced data...

By Wayne Overbeck, N6NB, Pepperdine University, Malibu, California 90265
what happens at uhf?

My quads-and-Yagis project really began as an attempt to develop an efficient antenna for the 432-MHz Amateur band. In 1970, I bought a 432-MHz Yagi of the only brand then commercially available, and optimistically took it to an antenna gain measuring session at the West Coast VHF Conference. The gain was measured at 6.4 dBi (dB over a dipole)—a shocking figure compared with the manufacturer’s claim of 13 dBi. What was wrong?

The element lengths and spacing seemed acceptable, if not optimum, and the SWR was below 1.5:1. Nevertheless, I finally replaced the driven dipole with a quad-type full-wave loop. The gain improved to almost 10 dBi (as measured at the next West Coast VHF Conference).

That led to the next logical step. I set up a backyard antenna range and set out to design a good 432-MHz cubical quad. After many frustrating hours, I decided I couldn’t come up with a combination of element lengths and spacing that would beat the hybrid quad-driven Yagi at 432 MHz. Up to four elements, the quads were competitive, but beyond that the quad-driven Yagi was better.

Note that I said I couldn’t design a quad that would beat the hybrid. A mere 4-element quad was superior to the original 11-element Yagi with its “stock” driven element on 423 MHz, even though the quad was less than half the Yagi’s length.

Finally, of course, I gave up on the quad and set out to optimize the quad-driven Yagi. Many hours and many designs later, the design that has come to be known as the Quagi emerged. Since the original publication of that design, the Quagi has been duplicated all over the world, with the design published in Amateur journals in such diverse countries as the Soviet Union, South Africa, and India.

At about the same time, a Danish scientist working in an anechoic chamber also observed the phenomenon that led to the Quagi antenna. He was working with antennas that combined loop driven elements and reflectors with three types of parasitic directors—loops, Yagi-type rods, and flat plates. He reported that for long-boom arrays (over two wavelengths), the loops were the least effective directors, although the difference was never greater than 1 dB.

free dB?

When the Quagi design was published, many Amateurs assumed its main advantage was a “free” 2 dB of extra “loop gain,” and that the gain of any Yagi could be improved 2 dB by replacing the driven element with a full-wave loop. This is not the case, unless the original dipole is less than adequate.

For instance, while the gain of the 432-MHz Yagi previously mentioned increases dramatically when the dipole is replaced by a loop, the same is not true of the 144-MHz version of that antenna. Replacing the two-meter model’s dipole with a loop results in almost no change in gain. At that frequency, it would appear the gamma-matched dipole is still a reason-
ably efficient driven element. Nor does the Quagi’s driven loop automatically ensure it 2 dB more gain than similar-size Yagis that have solved the feed problem in other ways. At 432 MHz, two of the 15-element Quagi’s toughest competitors in antenna gain competitions are the KLM 16-element log-periodic-driven Yagi, and the F9FT 21-element array, which has a large oval-shaped folded dipole sometimes called a “flattened quad.” What the vhf Quagi offers is the gain of a long-boom Yagi with an efficient driven element that can be easily duplicated using tools and materials readily available to Amateurs. It does not offer 2 “free” dB.

When most Radio Amateurs, and some commercial antenna builders, set out to build a conventional Yagi for uhf, the result may well be disappointing. Anyone who has attended a few antenna gain measuring sessions at vhf conferences has seen seemingly well-built 432-MHz Yagis measure very low gains, despite all indications that they should work well (i.e., good SWR, good E- and H-plane patterns, and so forth).

At 1296 MHz, building an efficient Yagi is even more difficult, and no commercial manufacturer currently attempts to do so for the Amateur market. But there is a commercial “loop-Yagi” available, an effective antenna of quad-type full-wave loops. For whatever reasons, quads seem to retain near-high-frequency efficiencies at higher frequencies than do conventional Yagis.

Nevertheless, in previous comparisons of quads and Yagis, much has been made of the results of uhf modeling, with authors sometimes citing the sophistication of their antenna ranges as evidence of the validity of their results. Now no one would question the principle of uhf modeling for designing antennas.
All of my antennas were experimentally optimized that way. One can derive good element spacings and lengths, and scale those values to lower frequencies, as long as frequency-related variables such as changing length-to-diameter ratios are not overlooked.

However, quad-versus-Yagi studies are a little different. Here someone is generalizing about the comparative performance of two different antennas at high frequencies on the basis of the comparative performance of uhf models of those antennas.

You can not consider it good engineering practice to compare two power transistors, for instance, at one frequency and then generalize about their relative performance at another frequency an order of magnitude removed. But our assumptions about quads and Yagis have been based largely on just such extrapolations! Those assumptions would be valid if quads and Yagis were equally efficient at high frequency and uhf (or declined in efficiency at the same rates). However, with antennas that exist in the real world, as with other rf-handling components, there may well be frequency-related variations in efficiency.

All one can really say, after a series of uhf experiments comparing quads and Yagis, is something like this: "These particular quads outperform these particular Yagis (or vice versa) in this frequency range." The fact that uhf modeling (including mine) tends to produce pro-quad results does not necessarily settle the matter on the 10-, 15-, and 20-meter bands.

### High frequency experiments

With these questions about comparative antenna data from 400 to 14 MHz in mind, I felt it was time to attack the quad-versus-Yagi question in a new way, by actually measuring the gain of quads and Yagis in operational high frequency installations.

Using the measuring techniques described in a previous article, I have rated the gain of several large 20-, 15-, and 10-meter antenna systems in Fig. 1. Briefly, the technique involves placing a directional reference antenna alongside each antenna to be tested (at the same height) and reading the strength (in dB) of a nearby signal as received by each antenna. The signal source is a directional antenna of the same polarization as the test and reference antennas, located at least 40 wavelengths, but not more than about 5 km distant. The receiver agc is disabled and its audio feeds a Hewlett-Packard 400L audio voltmeter.

How do you place a reference antenna beside various antennas that may be 70 or 80 feet in the air? The answer, of course, is a self-supporting crankup tower on a trailer. I just happen to own not one but two such monsters; they were built for portable contest operating.

As a reference antenna, I selected a 2-element tri-band Yagi (Hy-Gain TH-2) because reference dipoles sometimes "see" reflections that can produce misleading results when a more directional antenna will not. All results are relative to the 2-element tribander. Its gain was assumed to be 5.0 dBi at its center frequency on each band. If that gain rating is too high (or low), all the other numbers will be incorrect on an absolute scale, but correct in relation to each other, which is what really matters for our purposes.

### 20-meter results

If the cubical quad antenna was to look good anywhere, 14-MHz turned out to be the place. Among the antennas I measured was the 6-element quad (8 elements on 28 MHz) at WB6HSG. It has a 14.6-meter (48-foot) boom. Patterned after Landskov's design but with a second reflector (added because quad pioneer C.C. Moore advised WB6HSG that a second reflector would surely provide more coupling, and hence more gain and front-to-back
KGNA, which has a 9.1-meter (30-foot) boom and uses Lindsay’s spacing. K6NA (ex-W6MAR) has long been concerned about the quad’s seemingly poor performance. In fact, its apparent mediocrity provided inspiration for Landskov’s attempt to optimize the quad design. This is the quad Landskov specifically cited as an example of a poor performer in his article.

After Landskov’s research was completed, K6NA took the quad down and moved to a new home. When put back up, the quad retained the original spacing but used Landskov’s dimensions for the elements (which differ from Lindsay’s mainly in that the percentage differences between the driven and parasitic elements are greater). For whatever reason, the data in fig. 1 show that it still performs poorly. Both Landskov’s larger quad design (as adapted by WB6HSG) and a number of Yagis proved to be substantially better than this quad.

On 20, even my 2-element quad was disappointing, comparing unfavorably with the 2-element trap tribander (on a 2-meter [6-foot] boom) used as a reference!

15-meter results

On 15 meters (fig. 1B), the results were much the same, except that my 2-element quad squeaked past the reference tribander by 0.25 dB across most of the band. Neither big quad matched my 5-element Yagi on a 10.4-meter (34-foot) boom. At one embarrassing point (21.250 MHz), K6NA’s 4-element quad fell to within 0.1 dB of the gain of the 2-element trap tribander.

Both WB6HSG’s and K6NA’s quads appeared to be resonant below the bottom of the band. Since both were cut to Landskov’s dimensions and also provided their best SWR at 21.0 MHz, it appears his dimensions are too long on this band. WB6HSG has since shortened all his 15-meter elements and reports a much better SWR and front-to-back ratio in the phone band.

As on 20 meters, K6NA’s higher Yagi was tested and plotted on 15, but the results are not considered comparable. Still, an antenna like that helps to explain K6NA’s success in contests, doesn’t it?

10-meter results

On 10 meters (fig. 1C), my 2-element quad finally behaved like an antenna without traps, topping the little tribander by up to 1.5 dB. Nevertheless, fig. 1C could not be used to support Lindsay’s thesis. The top curve is a commercial 5-element Yagi on a 7.9-meter (26-foot) boom, little more than half the boom length of WB6HSG’s big quad. Incidentally, this Yagi was measured directly against the big quad. After I
compared the quad against the reference tribander, I lowered the portable tower and put up the 10-meter Yagi. The Yagi had the edge at every point in the band where we took a reading (each 100 kHz).

K6NA’s quad was consistently 2 to 2.5 dB down from the smaller Yagi. It did, however, outperform a 5-element Yagi at W6HX, but that antenna was known to be defective before my measurements, perhaps due to driven element problems. For contest work W6HX uses another 10-meter Yagi considered to be “1 to 2 S-units better,” but that antenna could not be measured due to logistics problems.

front-to-back ratios

Another claim often made for the cubical quad is a superior front-to-back ratio. The emphasis in the previous tests was on forward gain. We did measure the front-to-back ratio of WB8HSG’s long quad on 10 meters, since he felt it was particularly good on that band. It varied from 18.2 dB at 28.4 MHz to an excellent 28.1 dB at 28.8 MHz. For comparison, the source antenna for those tests, a Hy-Gain TH-6 tribander at N6MB, was rotated. Its front-to-back ratio varied from 19 to 25 dB across 10 meters.

While this test did not show the long quad to be dramatically superior to a tribander in front-to-back ratio, comparing my 2-element quad against the reference 2-element tribander did reveal a substantial edge for the quad. On all three bands, the quad exhibited in excess of 20 dB while the tribander never exceeded 14 dB.

high and low quads

When this data was first presented at a meeting of the Southern California DX Club, two questions were raised that led to additional research. First, someone pointed out that virtually everything I had done was at a height of about 21.3 meters (70 feet). “A quad really comes into its own is at low heights,” someone suggested.

Almost everyone who has written about quads has denied that a quad provides a lower angle of radiation than a Yagi.\(^{10}\) Nevertheless, I set up two 21.3-meter (70-foot) towers side by side near a body of salt water (at the Ventura marina) to test the relative performance of a quad and a Yagi at high and low heights. The over-salt-water site was selected to eliminate the possibility of actual ground being so far below the earth’s surface as to invalidate the experiment.

The result was conclusive; the relative performance of the quad and Yagi was exactly the same at both 7.6 meters (25 feet) and at 21.3 meters (70 feet)! This was true on zero-angle line-of-sight signals, high-angle “short skip,” and on long-haul DX signals. There was no height at which the quad’s relationship to the Yagi changed. The curves rating the two antennas could have been derived at any height between 7.6 and 21.7 meters (25 and 70 feet).

main-lobe centered tests

The other major question raised by the SCDXC members was really twofold: 1) my results might be invalid because I had been testing triband quads against monoband Yagis; and 2) my antenna ranges were, in effect, “ground-reflection” ranges, but that antenna was measuring signals at zero degree angles rather than up in the middle of the main lobe.

To determine if these factors were significant in my research, I set up another experiment. I selected a cleared construction site where the soil had just been leveled, a site on flat land about 500 meters from the foot of a hill. The vertical angle to the hilltop was about nine degrees, according to W6HX, who felt it was particularly good on that height. Roads traversed the hill at several elevations, permitting tests at other radiation angles between zero and nine degrees.

I chose 50 MHz for these tests in a tradeoff between the desire for results applicable to the high frequency spectrum and the desire to work with antennas having manageable dimensions. Since the construction methods, element and boom diameters, and wire sizes were essentially the same as those used at 14 MHz (as a percentage of the respective wavelengths), the results here would be expected to be similar to those in the upper high frequency bands.

I prevailed upon AA6DD and K6LPF to spend an afternoon and evening on the hilltop. Then AA6DD spent another day moving up and down the hillside, always with a 3-element, 50-MHz Yagi mounted on his car as a signal source.

These 50-MHz tests were interesting in several
Leafless trees give this photo of the antenna farm at WBHX an eerie feeling. At the upper right is the reference tribander positioned to match the height of one of the WBHX antennas for the gain comparisons.

respects. First, there was virtually no difference (±0.3 dB) in the comparative performance of the quads and Yagis tested at the various vertical angles from zero to nine degrees. In view of what has been previously written (and what I found) about the similarity of the vertical angle produced by quads and Yagis at any given height above ground, this result would be expected. It indicates that measurements can indeed be made with a local signal source (arriving at or near zero degrees) to produce results valid at higher angles, as long as the test and reference antennas are at the same height.

Perhaps the most interesting thing about the 50-MHz tests was the opportunity to compare a variety of well-known quad designs in a monoband configuration with a good 5-element Yagi as an on-site reference.

The results are summarized in table 1. The Lindsay and Landskov designs are those described in the articles already cited. The Machin "optimum" quad is a design recently published with the claim that it represents the true optimum spacing for quad arrays.11 The Machin spacing is 0.15 \( \lambda \) reflector to driven element, 0.30\( \lambda \) driven to first detector, and 0.30\( \lambda \) driven to second director. The longest 4-element quad is an outgrowth of my 432-MHz experiments. Its spacing is conventional (about 0.21\( \lambda \)) except between the first and second directors, where it is 0.49\( \lambda \). I used Landskov's element dimensions for this antenna. The 3-element quad is spaced 0.21\( \lambda \) and uses Landskov's dimensions.

In all cases, the element lengths were scaled from the original designs by determining the percentage differences from the driven elements and then applying those percentages to an experimentally derived correct length for a 50.1-MHz driven loop.

### 50-MHz summary

In these tests, monoband quads with short booms (up to about 0.5 wavelength) did indeed approach (but not equal) the gain of a longer Yagi. However, increasing the boom length still did not produce any quad that equaled the reference Yagi.

Neither Machin's long-boom quad nor mine delivered enough gain to justify its size. For all practical purposes, Machin's quad is identical in gain to the far smaller Landskov design, casting doubts on his claim that he has discovered the unique optimum design for a multi-element quads.

In fact, for an Amateur who could not accommodate a long-boom Yagi on his real estate, the Landskov quad design would seem to offer an excellent compromise. In this monoband version, it fell only 0.9 dB short of the 5-element Yagi. For comparison, a 20-meter Landskov quad is 9.75 meters (32 feet) long, while the Yagi would be 15.85 meters (52 feet) long.

Another good design appears to be the relatively wide-spaced 3-element quad shown in table 1. On 14 MHz it would fit on a 9.1-meter (30-foot) boom; it delivers excellent gain for its size and boom length.

It should be emphasized again, however, that these are monoband quads. The high frequency study indicated that the same results are difficult to attain in multiband configurations. And given the mechanical problems inherent in stacking monoband quads for several bands (with an acceptable stacking distance between the top of one quad and the bottom of the next higher one), stacked monoband Yagis still look pretty good for high performance on a variety of high-frequency bands.

### about trap tribanders

If this field research suggests that long Yagis are the most consistent high-performance antennas for serious DXers and contest operators, where does that leave the thousands of Amateurs who use trap tribanders? How good are these multiband Yagis?

To find out, I set up two manufacturers' top-of-the-line tribanders side by side. Using the same test procedures as in the other high-frequency experi-
ments, I ran gain curves on the two big tribanders. Then I replaced one tribander with the original reference TH-2 and repeated the experiment so the gain of the two big tribanders could be plotted on the same chart as the other antennas tested.

Perhaps the most notable conclusion, and the least controversial, was that these big tribanders sacrifice bandwidth for multiband coverage. Both were adjusted for phone band operation, using the factory-specified dimensions, and both exhibited drastic gain fall-off in the CW bands.

The results of the comparison produced no clear-cut answer for the Amateur who asks, "Which should I buy?" Tribander number 1 was much better on 20 meters, but slightly inferior on 15 and very inferior on 10. The poor showing on 10 can be explained in part by the owner's choice of the "high phone" length settings, but even at 29.4 MHz it was only 1.4 dB better than the reference TH-2, which was tuned much lower in the band! In fact, except for a couple of instances, the big tribanders exhibited very little gain above the two-element reference tribander! And both tribanders were markedly inferior to the monoband antennas, even in that very narrow range of frequencies where the tribanders hit their peak performance on each band.

None of this is new or surprising information, of course. But a look at the antenna gain charts could provide a dramatic illustration of the compromises involved in trap tribanders! If your goal is to keep in touch with friends and do some casual DXing, a tribander is fine. But if you want a first-rate signal, a trap tribander isn't the answer!

conclusions

These field experiments are by no means the last

Another source of big signals, N6NA (ex-W6MAR). At the left is the stack of Yagis which look as good on the gain plots as they do in the air. The 20- and 15-meter Yagis are considerably higher than the reference tribander, rendering the gain figures on these big beams invalid for comparison purposes. In the center is the 4-element quad, a source of much head scratching because of its questionable performance.
ones I’ll undertake to compare working quads and Yagis on the high-frequency bands. Any judgement at this point is necessarily tentative, subject to revision as more data is produced, but the following conclusions are justified:

1. Cubical quads do not “come into their own” at low heights. At any given height, the vertical angle of radiation of quads and Yagis is virtually identical. The old idea that quads are better low-height performers than Yagis should be recognized as the myth that it is.

2. As the frequency is increased into the uhf region, the performance of cubical quads and Yagis may not deteriorate at exactly the same rate, given the mechanical differences between the two designs, particularly their driven-element configuration. This creates difficulties that must be accounted for if you wish to generalize about the relative performance of the two antennas at the high frequencies on the basis of uhf modeling.

3. While it may be possible to design a high-frequency cubical quad with a long boom that will outperform a similar size Yagi by 2 dB as Lindsay suggested, no quad I tested approached that level of performance. In few cases did a quad of more than two elements even equal a comparable-size Yagi. The 50-MHz tests illustrate the difficulties of achieving gain increases, when a quad’s boom is lengthened, that equal the gain increases normally found when a Yagi’s boom is increased. In fact, the quad

High and low antennas by the sea. Each antenna is on a trailer-mounted crankup tower beside a salt-water marina, ensuring an electrical ground near the surface. Regardless of the height, the relative performance was identical.
seems to be at its best in two- and three-element designs.

The data presented here would support a conclusion not far afield from the assessment of quads versus Yagis in Bill Orr's original work on the subject some 15 years ago. In that first edition, Orr said that a 2-element quad was superior to a 2-element Yagi, but that larger quads were inferior to comparable-size Yagis.

In his 1970 edition, Orr qualified that conclusion considerably, and his latest antenna book, published in 1978, says flatly that quads are 2 dB better than Yagis. The new work has a "truth table" that simply rates the 4-element quad at 12 dBd and the 3-element quad at 10, with the corresponding Yagis 2 dB lower!

Neither our tests at 50 MHz, nor the 10-, 15-, and 20-meter tests at K6NA (both tests involving quads almost identical to the 4-element design in Orr's new book), would support that conclusion. I have yet to see a 4-element quad deliver 12 dBd gain or anything close to it on any frequency, or to outperform a well-designed 3-element quad by 2 dB, for that matter.

Perhaps there really is a high-frequency cubical quad out there somewhere that delivers 2 dB more forward gain than a well-designed Yagi of the same boom length, a quad that does what Orr, Lindsay, and others say a quad will do. Perhaps, but I tested quads built to the most popular published dimensions by respected Radio Amateurs and none of their antennas came close to beating a comparable-size Yagi by 2 dB. In many instances, even trap tribanders were comparable to quads of similar boom lengths, with full-size Yagis far better than either!

To those who still believe in the superiority of the quad antenna, I offer a challenge — bring me a high-frequency quad of four or more elements that you believe outperforms a comparable-length Yagi. I'll provide two towers in an open field for the side-by-side tests. If your quad really delivers 2 dB more than my Yagi, I'll publicly recant the conclusions presented in this article.

Acknowledgments

Many Amateurs cooperated in the time-consuming process of gathering data for this report. In particular, I would like to thank W6AQ, K6AV, WA6BTX, W6CG, AA6DD, W6ESQ, WA6FVR, WB6HSG, W6HX, WA6IHZ, K6LPF, N6MA, N6MB, K6NA, N6NT, W6OXY, and N6RS for their help. Without their field work, the charts and tables would be blank.

rf impedance bridge measurement
errors and corrections

How to determine the effects of stray reactance in rf impedance measurements and how to compensate for them

The current interest in various commercial and homemade impedance-measuring devices which measure both the real and imaginary components of impedance certainly represents progress toward higher-performance antenna systems. To attain the level of accuracy that these devices can deliver, however, it is necessary to appreciate the sources of error that can creep into a test setup and then correct for these errors. Unfortunately, few Amateurs seem aware of these problems, and consequently they accept their bridge readings as gospel.

Basically, there are two sources of error: those external to the measuring device (usually stray capacitance, which will cause any impedance-measuring device to read low), and those within the measuring device itself. Even the prestigious General Radio 916/1806 family of rf bridges has systematic errors which must be corrected for if accurate results are to be obtained. I was unpleasantly surprised when I finally got around to working out the predictable errors in my measurements.

benefits of bridge corrections

A user of an impedance-measuring device may ask, "Why go to all the trouble of calculating correction factors?" First of all, it does not take that much additional effort. If you want accurate measurements, you are going to spend a fair amount of time and effort putting together a good test setup; the additional time and effort to punch numbers into a calculator is minor.

In addition, you can get a great deal of personal satisfaction when your measured data falls right where the textbooks say it should. When this happens to me, I feel as though I really understand whatever I am working on and am really the master of it. This feeling of accomplishment is probably why I experiment in the first place — that and curiosity. Finally, when you are sure of your measurements and then get unexpected results, you can explore the device with a lot more confidence.

In the material that follows, I will discuss in detail the error caused by stray capacitance and give a calculator program to correct this error. I will briefly discuss instrumentation errors and give a procedure for calibrating a measuring instrument; discussions of calibration will necessarily be in outline form since the many types of instruments in general use will each require slightly different calibration procedures.

stray capacitance errors

The effect of any stray reactance, either capacitive or inductive, shunted across an impedance is to lower the apparent value of that impedance. Consider the impedance $Z_x = R_x + jX_x$ in fig. 1 with a reactance $jX_a$ shunted across it. In the discussion that follows, I will assume that all reactances are inductive (positive), as this simplifies the problem of algebraic signs. When a conclusion is reached, I will explain the changes, actually very minor, which are necessary for negative reacntances.

In fig. 1, $R_x$ and $X_x$ are the real and imaginary parts of the unknown impedance. The shunt reactance is represented by $jX_a$ and is presumably known, or at least estimated. The resulting impedance formed by $Z_a = |jX_a|$ (the parallel bars | | should

fig. 1. Diagram showing the stray reactance $\pm X_a$ shunted across an unknown impedance $Z_x = R_x \pm jX_x$. The text presents equations for compensating for the effects of $\pm X_a$.

be read "in parallel with" is given mathematically by
the well-known "the product divided by the sum" rule:

\[ Z_m = \frac{jX_u(R_x + jX_x)}{R_x + j(X_u + X_x)} \]

After rationalizing the denominator by multiplying
both numerator and denominator by the conjugate of
the denominator, the separation of the results into
real and imaginary parts gives

\[ R_m = \frac{R_x X_a^2}{R_x^2 + (X_a + X_u)^2} \]  \hspace{1cm} (1)
\[ X_m = \frac{X_a[R_x^2 - X_x(X_u + X_a)^2]}{R_x^2 + (X_a + X_u)^2} \]  \hspace{1cm} (2)

In actual practice, \( R_m \) and \( X_m \) will be read from the
bridge, so will be known. The stray reactance will
also be known, or at least estimated. \( R_x \) and \( X_x \) are
the unknown quantities. It will therefore be desirable
to solve eqs. 1 and 2 for \( R_x \) and \( X_x \). The algebra is
rather involved, so I will just give the results:

\[ R_x = \frac{R_m}{(1 - \frac{X_m X_a}{X_a})^2 + (\frac{R_m}{X_a})^2} \]  \hspace{1cm} (3)
\[ X_x = \frac{X_m - \frac{R_m^2}{X_a} - \frac{X_m}{X_a}}{(1 - \frac{X_m X_a}{X_a})} \]  \hspace{1cm} (4)

If the stray reactance is capacitive, \( X_a \) will be
negative, so that a negative sign should be used in
the above equations with \( X_a \); the same holds true for
\( X_m \). If there were no stray capacitance, \( X_a \) would
be infinite, so that \( R_a = R_m \) and \( X_a = X_m \).

Eqs. 3 and 4 do not require great mathematical
ability to solve, but the algebra is tedious when done
by hand, even with a pocket calculator. A program
can be written for a programmable calculator, how-
ever, that eliminates much of the burden (and many
chances for mistakes). An HP-25 program to solve
these equations is shown in fig. 2.

It will be seen that while the external corrections
may be minor when working with low-impedance
networks at low frequencies, the errors increase at
higher impedances and higher frequencies. The illus-
strative example given in the HP-25 program shows
that a correction of about 5 per cent in resistance and
the correction of the reactance term completely
changes sign from negative to positive. This example
is based on an actual measurement I made on an ex-
perimental balun. If I had tried to correct a negative
reactance in the balun when the reactance was actu-
ally positive, it is obvious I would have been wasting
my time! A situation like this can be very misleading.

Two final comments are in order: First, while shunt

reactance has been portrayed as a source of error,
the same shunting effect can also be used to advan-
tage to measure an equivalent series impedance that
is above the range of the bridge. The unknown impe-
dance is shunted down by placing a reactance, usu-
derly capacitive, in parallel with it. The unknown impe-
dance is then calculated by eqs. 3 and 4. The program
also calculates the shunt reactance for a fixed value of
stray capacitance and the variable parameter, frequency (see STO 0 and steps 3, 4, 5, and 6). Note that the sign
STO 0 must be negative because the stray reactance is capacitive. Before running the program
store \(-2 \times 10^{-6} \text{ in STO 0}\) and \(1 \text{ in STO 1}\). To run pro-
gram, key in \( R_m \) (ohms), press ENTER, key in frequency
(MHz), press ENTER, key in \( X_m \) (ohms with proper sign), and
press R/S. Calculator displays \( R_x \), at step 21, and \( X_x \), at step 31.
ternal to and independent of the impedance-measuring device. This error will occur whether you use a laboratory-type instrument costing several thousand dollars or a homemade device, built with parts from the station junkbox.

I will now discuss in a very general way errors that occur within the measuring instrument itself. The GR-916/1606 instruments will be used as a vehicle, but I will try to present the material in a manner that makes it applicable to any similar instrument, commercial or homemade.

All impedance-measuring devices (that I am aware of) have internal errors, especially at the extreme ends of their frequency or impedance ranges. The sources of these errors can be very subtle. For example, in the GR-916/1606 family, the principal error at high frequencies is caused by the changing effective series inductance of the RESISTANCE capacitor; i.e., the variable capacitor connected to the resistance dial. This inductance causes the effective capacitance to increase as the frequency increases, thereby causing the resistance dial reading for a given resistance value to read low. For the GR-916, this error alone can be as large as 30 per cent at 60 MHz and 100 ohms, for a typical instrument.

At the low-frequency end, the dielectric loss in the REACTANCE capacitor causes an effective series resistance that increases with higher REACTANCE dial settings and low frequencies, again causing the resistance dial to read low under some conditions.

Both these errors are predictable, systematic errors which exist in addition to any random, unknown errors caused by manufacturing variations or operator error. Graphs for correcting both types of errors in the GR-916/1606 are given in the instruction manuals and should be used if you want good accuracy. In addition, an equation for correcting the high-frequency error in a typical instrument is provided along with a procedure for obtaining the fudge factor for any particular instrument. I have programmed this equation on an HP-25 pocket calculator, but am not including the program here because of its limited interest. However, I will be glad to provide a copy to interested readers on receipt of a large, self-addressed, stamped envelope.

I feel certain that all impedance-measuring instruments have some systematic error. Just because the instruction manual for an instrument does not mention internal errors does not mean that there are none; it just means either that the manufacturer did not know how to determine it or he could not afford to work it out for the price at which he is selling the instrument. Actually, working out the instrument correction factors is not too difficult — and it is absolutely essential if you want to obtain accurate measurements.

In calibrating an impedance-measuring instrument, the most important item is a known value of impedance. For this, I use a Hewlett-Packard 906-A 50-ohm termination. This termination is an accurate 50-ohm resistor with negligible reactance well into the GHz region. This model uses a type-N connector; the cost is in the $25-30 range. Though this may seem expensive for a 1-watt resistor, the cost is small compared with what you already have invested in a commercial bridge. If your bridge is homemade, you may need a precision 50-ohm resistor more than you realize!

A second reason for using this type of calibrated load is that since the load has negligible reactance itself, you can accurately determine the stray reactance which must be known before accurate test data can be obtained.

If you want to avoid the expense of a laboratory-type termination, I suggest the use of the RN-55 family of Mil-spec resistors. These seem to have the lowest reactance of any family I have tried. They also have the advantage of being available in values other than 50 ohms.

The calibration procedure for a typical instrument is very simple; although it does not apply to the GR-916, it can be used with a GR-1606. Measure the impedance of the termination at various frequencies through your range of interest. Since it is necessary to know precisely the resistance and reactance presented to the bridge terminals, it is necessary to make corrections using eqs. 1 and 2. To do this, you must estimate the shunt capacitance, and this is where a reactance-free load comes in handy. Use eq. 2 first; assume values of $X_a$ corresponding to shunt capacitances of, say, 1, 2, 3... pF, etc. at your highest test frequency. Set $R_x = 50 \text{ ohms}$ or whatever resistance value you are using, $X_x = 0$, and calculate the values of $X_m$ for each capacitance. Compare these values of $X_m$ with the $X_m$ you measure, and when your calculated values of $X_m$ have bracketed the measured values of $X_m$, you have also bracketed the actual value of $C_a$. Now back up, say, 0.5 pF, and determine $C_a$ as accurately as you wish. Remember that since $X_a$ is capacitive, a negative sign should be used in all of the correction equations.

When you accurately know $X_a$, solve eq. 1 to calculate the resistive component of impedance appearing at your bridge terminals at each frequency; compare these against the measured resistance of the load and determine the correction factor for your instrument at each frequency. These corrections can then be plotted.

One difficulty in using a chart is that a chart cannot be programmed into a computer. It would be convenient to determine the equation of the correction curve so that it could be programmed into a calcula-
tor. It should be possible to do this and those interested may refer to a textbook on the subject. Thus both the bridge correction and the shunt reactance correction can be worked out in one calculation.

The advantage of having a reactance-free resistance can be seen. Your impedance-measuring device can only measure the reactance across its terminals; it cannot distinguish between stray reactance or a reactive component in the unknown impedance.

A note of caution concerning the order in which the corrections are made: when measuring an unknown impedance, the usual application, the bridge correction must be calculated first. Eqs. 3 and 4, which are used to calculate the stray capacitance correction, assume that the measured values are accurately known. On the other hand, when calibrating the bridge using a known value of resistance, the stray capacitance correction must usually be made first because you are trying to determine the actual impedance across the bridge terminals. The GR-916 appears to be an exception; I do not know why.

examples

At this point some examples should help clear up the details. The first example will demonstrate the use of a reactance-free termination to determine the shunt capacitance and show how this capacitance can differ from the measured value.

I was in the process of calibrating my GR-916 using an H-P 50-ohm termination. A photograph of my setup is shown in fig. 3. The stray capacitance to ground of the test lead and type-N coax connector measured 2.95 pF using a GR-821 admittance bridge.

At 54 MHz the impedance of the 50-ohm termination measured 40.3-j3.33 ohms on the GR-916 bridge. For a high quality termination, this appears way off, but let's correct it. Start with eq. 2. Set \( R_s = 50 \text{ ohms} \); assuming the stray capacitance to be 2.95 pF as measured, then at 54 MHz, \( X_s \) will equal \(-990.894 \text{ ohms} \). Solving eq. 2 gives \( X = -2.49603 \) as compared with \(-3.3333 \text{ ohms} \) measured. Hence the stray capacitance must be more than 2.95 pF.

Next try, say, \( C_s = 4.0 \text{ pF} \), and calculate \( X_s = -3.3774 \text{ ohms} \), again compared with \( X_s = -3.3333 \text{ ohms} \) measured. Back up a little and let \( C_s = 3.95 \text{ pF} \) and calculate \( X_s = -3.3355 \), which is very close. Since the test fixture measured 2.95 pF, the stray capacitance in the bridge must be 1 pF.
Assuming the stray capacitance is 3.95 pF, it is interesting to calculate the equivalent impedance looking into fig. 1. Use eqs. 1 and 2 and obtain \(R_m = 49.776\) ohms. The difference between this value and the 40.3 ohms measured by the bridge is the bridge error. The reason why the shunting effect is so small is that the shunt capacitance and resistance level are both relatively low.

I am not going to pursue this example further because the remainder is unique to the GR-916 and would have relatively limited interest, but I did want to demonstrate the value of having a high quality termination and how to use it in estimating stray capacitance.

My second example should be of special interest to users of baluns, particularly W2AU balun users. In this case I was measuring the input impedance of a W2AU 1:1 balun at the unbalanced end with various values of resistance connected across the balanced terminals. Table 1 gives the uncorrected bridge readings, the impedance with bridge corrections only, and finally bridge and stray capacitance corrections. A photograph of this test setup is shown in fig. 4.

The stray capacitance of the test fixture with a type-UHF connector and a male-to-male adapter measured at 5.3 pF; adding 1 pF for the bridge capacitance gives 6.3 pF. I am giving only the 30-MHz measurements.

Comparing the original bridge reading with the fully corrected data shows as much as 10 per cent correction, approximately equally divided between instrumentation and stray capacitance effects.

Comparison of the load resistance and final data columns will be of interest to those using 1:1 baluns. It shows the necessity of matching the balun impedance to that of the load and transmission line. This is a need that is just beginning to be recognized. I believe this data is typical of ferrite-rod baluns, but that's another story.

## Conclusion

Impedance-measuring devices can be very useful for matching antennas as well as in many other applications around the ham shack. Their results, however, must be treated with caution because even the best instruments and test setups are subject to errors. The most predictable source of error caused by the test setup is stray capacitance; this effect can only be minimized, not eliminated. Equations have been presented for calculating the true impedance in the presence of stray capacitance. Possible instrument errors have been discussed in a general way, and a possible method described for correcting these errors as well.

The program for computing the true impedance in the presence of stray capacitance on an H-P 25 programmable calculator is probably usable on other H-P calculators, although the keystroke numbers may be different. I do not have programs for calculators of other manufacturers.

Ham Radio
We are proud to introduce the newest member of our famous Thunderbird line of Tri-Band antennas. The THSDX offers outstanding performance on 20, 15, and 10 meters. It features 5 elements on an 18 foot boom, with 3 active elements on 15 and 20 meters and 4 active elements on 10 meters. The THSDX also features separate air-dielectric Hy-Q traps for each band. This allows the THSDX to be set for the maximum F/B ratio and the minimum beam width possible for a Tri-Band antenna of this size. Also standard on this antenna are Hy-Gain's unique Beta-match, rugged Boom-to-mast bracket, taper-swaged elements and improved element compression clamps.

Boom length ................. 18 feet
Longest Element .............. 31 feet
Turning Radius ............... 18 feet
Surface Area .............. 6.4 sq. feet
Wind load .............. 164 lbs.
Weight .............. 50 lbs.

VSWR at resonance .......... less than 1.5:1
Power Input .............. Maximum Legal
Input Impedance .............. 50 ohms
-3dB Beamwidth .......... 66° average
Lightning Protection ...... DC ground
Forward Gain .............. 8.5 dB
Front-to-Back Ratio .......... 25 dB

broadband reflectometer and power meter

Construction details for a combination peak-reading power meter and broadband SWR bridge

The reflectometer design described in this article uses a coupler technique that has not received attention in the Amateur literature worthy of its versatility, simplicity, and useful characteristics. Apart from being easy to construct, this design covers a three-decade frequency range, from 100 kHz to 100 MHz, and can be constructed with a power sensitivity as low as 500 mW or as high as 500 watts.

The problem with most high-frequency reflectometer designs, in the experience of the authors, is that they generally cover only a frequency range of a decade or less — usually 3 to 30 MHz. Many are quoted as covering well into the vhf range (usually to 150 MHz), but, in practice, they suffer from rather extreme errors in accuracy due to construction discontinuities as well as from large sensitivity excursions across the range.

The predominant technique employed in most published Amateur designs, and in many commercial designs, is to have one or more secondary “coupling” lines inserted into a short length of coaxial transmission line. The well-known Monimatch uses this principle. Two insulated wires are simply slipped under the braid of a short length of coax to form

By Roger Harrison, VK2ZTB, and Phil Wait, VK2ZZQ. Mr. Harrison’s address is 14 Rosebery Street, Balmain, 2041, NSW, Australia. Mr. Wait can be reached at 6 Church Street, Balmain, 2041, NSW, Australia.
coupling lines which sense the forward and reflected components of standing waves on the transmission line.

A similar method, popularly used in commercial designs, is to construct a section of coaxial transmission line from a sheet metal trough with two short coupling lines supported parallel to the center conductor.

Apart from construction discontinuities, the technique suffers from two serious drawbacks. The coupling coefficient of the secondary lines varies with frequency, being least at the low frequencies and rapidly increasing as the length of the coupling lines becomes a significant fraction of a wavelength. Secondly, the technique suffers from ever-decreasing accuracy at the higher frequencies for similar reasons, and poor sensitivity at the lower frequencies reduces the accuracy at low standing-wave ratios.

Properly engineered and constructed, reflectometers using this technique can have excellent characteristics and accuracy across a bandwidth of as much as several octaves. Getting them to perform consistently across a decade or more is tantamount to magic – you rapidly run into the law of diminishing returns.

design points

Although the technique employed in the coupler of this reflectometer has been around for a number of years, it has received inadequate attention in the literature. The basic requirement for a reflectometer is that it generates two voltages which are proportional to the forward and reflected voltages or currents existing in the transmission line under measurement. Techniques employed to fulfill this requirement use either voltage or current deflectors coupled to the transmission line to produce two out-of-phase signals, since the forward and reflected components on the transmission line are 180 degrees out of phase.

This reflectometer employs a current transformer constructed as follows. A short length of coaxial cable is passed through a ferrite toroid forming the primary. The braid, or outer conductor of the coax, is connected to form an electrostatic shield. The secondary consists of a winding around the circumference of the toroid which couples to the magnetic component of the leakage field of the short length of coax cable.

The load on the current transformer secondary is center-tapped so that out-of-phase signals appear at each end of the secondary. The load center-tap is returned to a voltage divider which samples the rf signal on the transmission line to perform the addition and subtraction across the load, yielding the forward and reflected components.

From this, the SWR may be computed from the following equation:

\[
SWR = \frac{E_f + E_r}{E_f - E_r}
\]

where

\[
E_f = \text{forward voltage components}
\]

\[
E_r = \text{reflected voltage components}
\]

Although a current transformer is employed, for

fig. 1. Schematic diagram of the broadband reflectometer and power meter. A specially configured switch was used for S1 (C&K type 7211); otherwise a double-pole, triple-throw switch will be necessary. The meter has a basic scale of 50 µA, with an internal resistance of 2000 ohms. The sensitivity pot (R8) should have a logarithmic taper. Transformer T1 is wound with 40 turns of number 35 AWG (0.14 mm) enameled wire over a Neosid type 28-511-31-F14 material toroidal core (initial permeability of 220). The measurements (outside diameter, inside diameter, thickness) of this toroid are 12.7 x 6.35 x 3.18 mm (0.5 x 0.25 x 0.125 inch). It is available from Neosid Limited, 10 Vansco Road, Toronto, Ontario, M8Z 5J4, Canada. C2 is a small mica compression trimmer.
convenience the detected components are presented as voltages.

**circuit description**

The secondary of the current transformer drives a center-tapped resistive load (R2, R3) connected to a voltage-sampling network (C1-C2/C3) across the rf input such that sum and difference voltages will appear across the ends of the transformer (see fig. 1). The two diodes, CR1 and CR2, rectify the sum and difference voltages, with rf and audio bypassing being provided by C4 and C5. A dc return for the diodes is provided by RFC1.

Power measurement is made by rectifying a portion of the rf voltage tapped off the line by the resistive divider, R5, R6. CR3 and C6 form a peak detector, as the load, R7 and the meter, is very light. CR4 and CR5 provide protection for the meter.

Some published designs use a resistive tap across the line to sample the rf for the current transformer load. At low powers, however, the low-resistance dc return of RFC1 provides better sensitivity.

The power rating is limited principally by the voltage breakdown characteristics of the coax line through T1. Standing-wave ratios greater than 3:1 generate substantial voltages across the transmission line, and any high-power operation with high SWR values should take this into account.

The sensitivity bandwidth is limited by the permeability of the toroid and the number of turns on the secondary winding. If this reflectometer is constructed for use at higher power levels, the sensitivity bandwidth is considerably improved.

Construction is very straightforward. The printed circuit board design shown in fig. 2A is recommended; otherwise, variations in construction may affect performance, particularly at the higher frequencies. As can be seen from fig. 2B, the components are mounted on the copper side of the board. Once all the components are soldered into position, the board is attached to the coax sockets and mounting bolts.

The toroid current transformer's secondary should be wound first. Following that, the coax primary should be assembled. Cut a 45-mm (1-3/4 inch) length of RG-58/U (single shielded), stripping back the braid and insulation as illustrated in fig. 3. Refer also to the component overlay and photographs. This operation is not all that critical, but it is advisable to follow the diagrams. Slip the toroid over the short length of coax and solder the coax and T1 leads to the printed circuit board as illustrated in fig. 2. Position the toroid centrally and attach it to the coax and board with a small amount of pliable rubber cement. Follow this by mounting all the other components.
The printed circuit board is mounted in a metal box on which two suitable coax connectors have been mounted. The printed circuit board is soldered to the center pins prior to securing the assembly with the two mounting bolts. To avoid undue stress, which can cause problems following assembly, coaxial plugs (assembled with cables) should be inserted into the two coax sockets when soldering the board to the center pins. Make sure that a good fillet of solder secures the pins to the printed circuit board IN and OUT pads.

The board is mechanically secured by two mounting bolts (shown in fig. 2 and the photos). A nut is placed under the board on each mounting bolt and a second on top of the board. This also serves to ground the board groundplane. Solder the top nuts.

The drawings show mountings for two SO239 sockets, although any of the other popular series of connectors may be used. However, center-to-center spacing of the sockets should be maintained at 60 mm (2.3/8 inches). The reflectometer was mounted in a 100 x 75 x 50 mm (4 x 3 x 2 inch) aluminum box. The meter used has a 50 x 50 mm (2 x 2 inch) face, but a larger unit, offering better accuracy, may be used, although this would necessitate a larger box.

calibration

A suitable rf source, a dummy load, and an rf voltmeter or an accurate rf power meter will be required for calibration.

SWR Scale. The instrument is connected between the rf source and the dummy load, the rf to the IN socket and the dummy load to the OUT socket. The sensitivity control should be set fully counterclockwise. The switch should be set to read forward power.

With the rf source on, rotate the sensitivity control clockwise until the meter reads full scale. Now, switch to read reverse power; adjust the trimmer, C2, to obtain minimum meter reading, increasing the sensitivity as the meter reading decreases. You should be able to reduce the meter reading to zero or very near.

![Diagram](image)

fig. 3. Dimensions for the section RG-58 of coaxial cable used as the primary of the transformer.

Once this operation is completed, the reflectometer section is calibrated. The photo shows the calibrated meter scale we attached to the meter face.

Any meter scale can be calibrated by using table 1 or the SWR equation.

Power. Fig. 1 shows a divider network which samples the rf voltage on the transmission line. The lower divider resistor is shown as a trimpot. A deposited-carbon type was used, but a fixed resistor may be substituted. The trimpot was set so that the full-scale meter reading corresponds to a particular peak power measured by another method (a borrowed power meter or rf voltmeter across the dummy load).

R6 values for particular full-scale power readings are given in table 2. The power scale should be calibrated to suit the individual instrument, as it will be nonlinear, the nonlinearity depending on the particular diode used for CR3.

May 1979
The current transformer response is essentially aperiodic, with the -6 dB points (compared with midband) from 200 kHz to 40 MHz (see fig. 4). This unit has a midband full-scale sensitivity of 500 mW (sensitivity control at maximum). At 50 MHz less than 5 watts is required to carry out measurements, even with low SWR values.

The inherent impedance of the unit was measured using a 5-watt TEK dummy load and a Hewlett-Packard vector impedance voltmeter. The results are illustrated in fig. 5. The impedance discontinuities displayed are well within the accuracy limitations of the meter movement. The real (or resistive) component of the reflectometer's impedance is within 5 per cent of the nominal 50 ohms — most of this variance probably is due to connector and construction discontinuities.

The variation in the real part of the impedance is within ±1 ohm across the frequency range and can be essentially ignored. The reactive component is negligible up to 30 MHz, at which point it begins to become slightly capacitive. This is largely immaterial. The overall impedance decreases rapidly above 100 MHz.

The short length of coax through T1 is "short" compared with the wavelength at 100 MHz, and it is physical discontinuities that contribute to the inaccuracies measured, becoming significant around 100 MHz. The SO239s used aren't constant-impedance connectors, and they probably contribute as much as construction to the upper-frequency limitation.

possible modifications

For higher powers, the sensitivity of the reflectometer may be varied by one or several of the following methods. For power around 20 to 50 watts, R2 and R3 should be reduced to 47 ohms. For powers above this, the number of turns on the toroid should be reduced. As a guide, twenty turns on T1 with R2 and R3 down to 47 ohms should prove adequate for powers in excess of 150 watts.

The basic reflectometer construction is so simple and inexpensive that several could be built to provide remote monitoring of individual antenna installations. Protection circuitry for transceivers and power amplifiers may be simply implemented using the basic reflectometer circuit driving protection circuitry from the outputs of CR1 and CR2. It is possible to use the reflectometer for swept VSWR measurements by using the differential output of CR1 and CR2.

Accurate measurement of VSWR values below 2:1 can be made by driving an expanded-scale differential voltmeter circuit as described in reference 2. This type of measurement is useful when measuring the VSWR performance of an antenna over a narrow bandwidth, particularly narrow-band loaded whips used for mobile applications.

The basic sensitivity bandwidth may be shifted up in frequency by a decade or more such that it rolls off around 1 MHz at the low end and above 50 MHz at the high end by using a toroid having a permeability of 50 rather than 220.

new approach to measuring SWR at high frequencies

A new type of sampling bridge for measuring power and SWR provides linear response and high directivity

In the past, VSWR measurements were made mainly to check antenna matching characteristics. Therefore, these measurements were performed at fairly high levels, with a directivity of 26 dB being sufficient. The new circuit design in this article provides low-level VSWR measurements between 30 watts and 30 mW incident or reflected power with a directivity of 40 dB.

applications

After the introduction of highly linearized transistors, wideband transformer techniques to cover 1.5 to 30 MHz became increasingly important. Wideband power stages, with exceptionally low intermodulation distortions, are required in test instruments, antenna distribution amplifiers, and ssb transmitters. Because there is higher feedback in transistor circuits than in vacuum tube designs, the return loss of the matching transformer plays an important role. Slight matching changes will degrade the intermodulation distortion performance. Therefore, it has become vital to measure the properties of wideband transformers over a large frequency, power, and directivity range. So far, no instrument has become available that will easily measure these parameters.

circuit description

The initial bridge arrangement for measuring the forward and reflected voltages (power) on a transmission line was invented in Germany by Dr. Buschbeck more than 30 years ago (see fig. 1). The obvious disadvantage of this circuit is that the two output ports have a fairly high impedance and are very sensitive to loads. Resistive loads below 10 kilohms will significantly disturb the directivity as well as the frequency response. This requires special diodes for high resolution. Also, this type of power meter suffers from the disadvantage that the power reading is highly nonlinear and depends very much on the mechanical configuration. The other disadvantage caused by the high impedance is that there is always fairly high cross-talk between both output ports, which effectively limits the directivity to about 26-30 dB.

In an effort to overcome the rectification nonlinearity, a special version of the tunnel diode, called a

By Ulrich L. Rohde, DJ2LR, 52 Hillcrest Drive, Upper Saddle River, New Jersey 07458
"backward diode," was used. Backward diodes* have virtually no threshold voltage and exhibit an extremely good approximation to a square law characteristic between a few μV and several mV. However, back diodes used as rectifiers have an extremely low impedance and therefore will load the circuit.

![Diagram](image)

**fig. 2. Diagram of a new bridge arrangement that employs back diodes and a transformer voltage divider. This configuration provides wide frequency response and high directivity. The transformers are wound on TCS-type ferrite cores. This is the circuit used in the Rohde & Schwarz NAUS 80 rf power meter.**

Because of this loading effect, an attempt was made to use a compensated RC voltage divider, as used in oscilloscopes. This was not successful, however, since the required flatness of output voltage tracking and frequency could not be achieved.

Analyzing Dr. Buschbeck’s circuit, it is obvious that the primary limitation is a result of the capacitive voltage divider, which, as a side effect, limits the cut-off frequency at the lower end of the frequency range. To overcome this limitation, a transformer was employed as a voltage divider, which led to the circuit shown in **fig. 2**.

The advantage of **fig. 2** is that both outputs are now terminated in 50 ohms, providing the necessary low impedance for the back diode rectifier. The inductive voltage divider provides a significantly flatter frequency response. In addition, since all impedances are now 50 ohms, the cross-talk is also reduced, allowing directivity of 40 dB.

This new technique can be used effectively to measure the characteristics of wideband transformers and power amplifiers under actual operating conditions. Network analyzers presently on the market are not capable of measuring at this low frequency range and high power level.

*A description of the back diode can be found in the Hints and Kinks section of QST for April, 1978.

**Larsen Küırod.**

the antenna that keeps its cool!

Looking for a mobile antenna that goes on easily, looks super . . . and performs like gangbusters? Then you should take a squint at the Larsen Küırod Antenna. It’s the cool one.

Yes, the fact is that Larsen Küırod Mobile Antennas are built differently for a communications difference you can HEAR. You can easily prove it to yourself with this simple touch test:

Apply 100 watts of power for a full minute or so to a competitive brand Antenna A, B, or C . . . any brand with the usual stainless steel whip. Then turn off the power and feel the antenna . . . carefully. It’ll likely be hot, even hot enough to raise a blister.

Now put a Larsen Küırod to the same test. Surprise! That’s right . . . no heat! The power has gone into communicating—not heating. The Larsen isn’t called the Küırod for nothing.

Larsen Antennas fit all styles of mobile mounts and cover Amateur frequencies from 10 meters through the 440 MHz band.

folded umbrella antenna

An effective, easy-to-build, all-band amateur antenna based on the principles of the folded unipole used in the broadcast service

A survey of amateur antennas would probably show that 95 per cent of them fall into one of four general categories:

1. Horizontal dipole (including inverted vee)
2. Vertical (ground mounted and ground plane)
3. Yagi (multiband and monoband)
4. Quad (multiband and monoband)

The folded umbrella falls into none of these groups—yet, when you see what it can do, you'll wonder, "Why not?" This article describes a versatile antenna that is:

1. Broadband on all frequencies, 1.8 through 30 MHz
2. Easily tuned
3. Fully effective without ground radials
4. Without critical dimensions
5. Simple, inexpensive, and easily erected by one man
6. Space saving
7. DC grounded
8. Adaptable to your tower

It seems that most homes lack the space required for a 3.5-4 MHz dipole, or for the ground radials needed to operate a conventional series-fed vertical antenna efficiently. The folded umbrella has evolved from the effort to overcome these space problems.

The first step was to consider an antenna used in the commercial-broadcast field and known as a folded unipole. Shown in fig. 1, it is a grounded broadcast antenna tower, with steel arms across the top which are connected electrically to the tower. Wires are connected to the ends of these arms and dropped to the bottom, forming a cage around the tower that is insulated from the tower at all points except the top. The cage wires are tied together at the bottom and fed directly at that point with 50-ohm coaxial cable. The advantages claimed for this antenna are as follows:

1. Broadband performance
2. Low radiation-angle
3. Elimination of expensive base insulator
4. Elimination of approximately 6100 meters (20,000 feet) of copper wire
5. Elimination of expensive matching network and weatherproof housing

These features are important to the operator who's trying to put a broadcast station on the air with limited funds.

the result

The folded umbrella is simply the result of several approaches to the development of an antenna which is, roughly, the electrical equivalent of the folded unipole. The outcome of the evolution process is shown in fig. 2.

design considerations

In the interest of simplicity and economy, this antenna was built around a 12-meter (40-foot), four...

By John M. Haerle, WB5IIR, Route 2, Box 348, Frisco, Texas 75034
section, telescopic or pushup TV receiving-antenna mast. In the development process, it soon became evident that the cage wires could best be supported by the nylon guys. Thus, the wires were pulled much farther away from the center mast—a fortunate accident as will be seen later.

Also, a 4.6-meter (15-foot) aluminum top-loading whip was added at the 12-meter (40-foot) level, making the antenna 16.8 meters (55 feet) high. The antenna will work well enough without the top loading, but the whip lowers the radiation angle and improves efficiency, especially at frequencies below 7 MHz.

Note that this antenna is not to be confused with the conical monopole or the discone. It is not within the scope of this article to discuss the differences, but they are well covered in reference 1.

**tuning and matching**

The commercial broadcast version of the folded unipole requires no variable tuning or matching arrangement, since it’s designed for a single frequency. However, to match the folded umbrella on any frequency across all six high frequency amateur bands, a tuned open-wire line and transmatch unit are used. Fig. 3 shows four different transmatch and feedline combinations. Fig. 3A is the basic configuration, using an unbalanced transmatch. In this configuration, be sure that the side of the feedline grounded at the antenna is the same side that’s connected to the ground terminal on the transmatch.

Fig. 3B illustrates the use of a balanced transmatch. In this case, a 4:1 balun is used at the antenna to maintain a balanced condition on the feedline.

Fig. 3C shows an arrangement which, theoretically, should unbalance things and bring unwanted rf fields into the shack. However, it has been tried and found successful in some cases. As a matter of fact the experimental antenna, which has drawn so much favorable mail, is operated in this manner. Note the balanced transmatch, and no balun at the antenna.

Fig. 3D shows the use of a short length of coax when it’s inconvenient to bring open-wire line into the station. Keep this coax as short as possible. The open-wire part of the feedline should be, ideally, about 20 meters (65 feet) long (or a multiple thereof). When using other lengths it may be difficult to obtain a 1:1 swr on some frequencies, especially the higher frequencies. If this happens, experiment with slightly different line lengths of plus or minus 0.9-3 meters (3-10 feet) until it becomes easy to obtain 1:1 swr on virtually any frequency.

**performance**

Performance of the folded umbrella is quite gratifying. When operated properly, the swr should be 1:1, and your rig should see a 50-ohm resistive load on all hf amateur frequencies. On 1.8 MHz, the folded umbrella substantially outperforms a half-wave inverted vee, whose apex is 15 meters (50 feet) above ground. For all other bands, the comparison antenna is a multiband inverted vee, 40 meters (130 feet) long, 15 meters (50 feet) above the ground, with tuned feeders and transmatch.

From 3.5-4 MHz, the inverted vee is generally better up to 805 km (500 miles) because of the high radiation angle of the inverted vee or the low radiation angle of the folded umbrella. Between 805-1610 km (500-1000 miles) the superiority of the two antennas alternates depending on propagation conditions. Beyond 1610 km (1000 miles) the folded umbrella takes over, its superiority improving with increasing distance.

From 7-7.3 MHz, the folded umbrella definitely outperforms the inverted vee at any distance. It appears that the diamond shape of the wire cage begins to provide a measure of cross-polarization from 7 MHz up resulting in the following:

1. A diversity effect, which minimizes fading on the transmitted signal
2. A much better snr on receive because of the closed-loop design and because the antenna is dc grounded
3. Broadband performance. For example, if the folded umbrella is tuned for a 1:1 swr at 7.150 MHz and the transmatch is left untouched thereafter, the maximum swr observed at either 7.000 or 7.300 MHz is 1.2:1
The experimental model was not used much between 14 and 30 MHz since a quad is generally used on these bands, but performance is comparable to that of a dipole on these frequencies. Other builders have reported excellent DX results on the upper bands.

**operation without transmatch**

The folded umbrella is basically a 3.5-4 MHz antenna. If it is fed directly with coax and no transmatch, the swr is less than 2:1 at both 3.5 and 4 MHz. From 1.8 to 2 MHz the coax-fed antenna shows an swr of approximately 2:1. On the 7-MHz band, swr is in the 2.5:1 range. At 14.2 MHz, swr is 5:1, at 21.3 MHz, swr drops back to 1.5:1, and on 30 MHz, swr is about 3:1.

Since none of these swr numbers is really high, a transmatch and tuned feedline can easily subdue them, resulting in 1:1 swr across all six bands.

**using your tower**

By applying unipole principles, you can use your tower. Just start by connecting one wire at some arbitrary point on the tower, say 12 meters (40 feet)

---

**fig. 2.** Construction details of the folded umbrella antenna, which is, roughly, the electrical equivalent of the folded unipole. Dimensions are approximate and are not critical.
above the ground. Use nylon line to pull the wire away from the tower. Then, bring the wire back to the bottom of the tower, as shown in fig. 4.

Use an exciter/vswr meter and a bridge or a grid dipper to check the resonant frequency. If it falls within the 3.5-4 MHz range, add the other three wires and proceed as with the folded umbrella. Your beam should provide adequate top loading. Be sure to ground the tower well.

**Construction**

1. Set up the collapsed pushup mast, using 6-mm (1/4-inch) nylon guys on all four sides. Use the closely woven nylon, not the loosely braided type. The former is much stronger and will not unravel. Do not use other synthetic line. Some of the other kinds of line become brittle with exposure to sunlight and will eventually break, while nylon retains its strength indefinitely. Nylon will stretch, but the close-woven type requires tightening only a few times initially.

2. Place the guy anchors at least 9 meters (30 feet) from the base of the mast (or use the house or trees where possible). Tighten the bottom guys firmly and place your ladder against the mast for further work.

3. Metal rings are supplied on the TV mast for attachment of guys. Be sure these rings are now in place before proceeding.

4. Insert 4.6 meters (15 feet) of aluminum tubing into the top of the pushup mast. This tubing can be made up of two or three telescoping pieces, if desired, just so long as the bottom (largest) piece fits snugly inside the top section of the pushup mast. The tubing can be secured by drilling through and bolting or by slotting the pushup mast and using a clamp (see fig. 5).

5. Attach four nylon (close-woven) guys to the top guy connection ring (fig. 5).

6. Pull the top section up out of the collapsed mast assembly about 0.6 meter (2 feet) to facilitate connection of the umbrella wires.

7. Tie two small loops in each of the four top nylon guys as shown in fig. 2. These loops should be about 4 and 8 meters (12.5 and 25 feet) from their attachment points on the mast.
8. Install umbrella wires.* Use approximately 16.8 meters (55 feet) of wire for each of the four elements. Clean and tin about 5 cm (2 inches) at one end of each wire. Clean and sand the mast just under the guy attachment ring. Using a stainless-steel hose clamp, attach the umbrella wires, spacing them equally around all four sides of the mast (fig. 5). Smear silicone rubber cement (GE or Dow-Corning) liberally over the hose clamp and bare wire ends to prevent corrosion of the electrical connection.

9. Thread one of the antenna wires through the two loops on each of the guys. You are now ready to begin raising the mast.

10. Use heavy leather gloves and be very careful when pushing the mast up. Whenever you stop the mast part way up, be sure to tighten the locking bolt very firmly, using pliers or a sufficiently large crescent wrench. If the mast should slip unexpectedly, it can pinch and cut your hand most painfully. This is the reason for the heavy leather gloves.

11. As you raise the mast, temporarily secure the bottom ends of the umbrella wires to their respective guys with tape. Then, keep these four wire/guy assemblies tied away from the mast as you raise it. This prevents the wires and guys from becoming tangled during the erection of the mast.

12. Now, push the top section up to its full length. There will be a hole at the top of the next section below. When the bottom of the top section is pushed high enough to clear this hole, push a large cotter pin (provided in the mast hardware) through this hole. Spread the ends of the cotter pin only enough to secure it, which will make it easy to remove at some later time. Now, tighten the locking bolt firmly. Repeat this process on the other sections.

13. Push the next section up and secure as above.

14. Attach four more 3-mm (1/8-inch) nylon guys to the ring at the top of the section just above the bottom section. This set of guys will end up, on full erection, 6 meters (20 feet) above the ground (fig. 2).

15. Push this last section up and secure, as above, and temporarily secure all guys.

16. Now, provide a bracket at the base of the mast for the purpose of connecting the four umbrella wires together while insulating them from the mast. This is the feedpoint for the antenna. One suggested method of anchoring and insulating the feedpoint is shown in figs. 2 and 6. However, as with other parts of this project, there are many different mechanical arrangements which will produce the same electrical results. Use your ingenuity. Remember, none of the dimensions are really critical, since the tuned feeders compensate for physical variations. If you're following fig. 6, however, pull the umbrella wires through the PVC tubing, tighten the clamp below the tubing, and trim off excess wire, leaving several cm of wire below the clamp. Now, bare the wires below the clamp and solder them together.

17. Drive three or four 2.4-meter (8-foot) ground rods around the base of the mast and connect them

*Any available type of copper wire up to 2 mm (no. 12 AWG), solid or stranded. The experimental model uses surplus 1.3 mm (no. 16 AWG) stranded, insulated wire.

fig. 5. Detail showing attachment of top guys, "umbrella" wires and top loading whip.

fig. 6. Mechanical details at the bottom end of the TV mast. The ground rods are essential for good performance.
securely to the mast with heavy copper wire, tubing or strap (fig. 6).

18. Attach feedline, soldering one side to the feedpoint and connecting the other side to ground. The most practical line to use is the 450-ohm plastic ladder line made by Saxton. It is strong, flexible, and much easier to use than bare open wire while just as effective. Furthermore, it's affected very little by ice, snow, or rain, as far as tuning is concerned. Figs. 2 and 7 show a simple, practical way of supporting the line. For the experimental model, it was necessary to run the line 18 meters (60 feet) to the house, keeping it at least 3 meters (10 feet) above ground. To relieve tension on the line, 3-mm (1/8-inch) nylon was threaded through the holes in the line and stretched from the mast to the house, serving as a "messenger" cable. Here again, use your own ingenuity to fit your situation.

19. After tuning and testing, tighten and secure the guys, using a plumb level to be sure the mast is vertical.

closing remarks

Here is an antenna that can do many things for you. Don't expect it to perform like a beam — but it will more than hold its own against conventional dipoles and trapped verticals at all frequencies and on all high frequency amateur bands.

I have received literally hundreds of inquiries from people who were impressed with what they heard when I was using the umbrella antenna. All inquiries have been answered, and those who have built the antenna report equally gratifying results.

The writing of this article was deliberately delayed pending receipt of data from others to provide the reader with authentic, reliable information.

reference

80-meter broadband antennas

A discussion of different approaches to broadbanding 80-meter antennas, including theoretical calculations and actual model measurements

Judging by the horrendous congestion that can be found on the 80-meter band almost any evening, it is certainly one of the most popular bands. But all of its users share the same problem with antennas. The ratio of the upper limit of the band to the lower limit is 1.143:1, larger than that of any other high-frequency Amateur band. Building an antenna which has adequate bandwidth for the entire 500 kHz may seem like an impossibility.

Years ago, transmitters had a very large range of matching capability. This luxury disappeared when the compact transceiver appeared on the scene over ten years ago. The problem has been compounded by the introduction of transmitters with solid-state power amplifiers requiring a load very close to 50 ohms. Protection circuits are normally employed to reduce the driving power to avoid damage to the output transistors. The use of a transmatch will eliminate the mismatch problems, but takes away the convenience of frequency changes without retuning.

The antennas shown in this article exhibit acceptable impedance matches over much more than the usual bandwidth. Although these designs may not be the perfect solution in every installation, they should provide starting points for further experimentation.

Current designs in use

One of the classic ways to increase the bandwidth of a simple dipole is to enlarge the effective diameter of the conductors in the radiating elements. The cage antenna is one example of this, in which each half of the dipole is made of several conductors. The multiple conductors are suspended on spreaders at two or more places. This simulates a conductor of roughly the diameter of the spreader. The fan dipole, or bow-tie, antenna is a simplification of the cage arrangement. In this design, each half is composed of two wires joined at the feedpoint. The wires fan out from this point and are held apart by a single spreader at the far end. Antennas of this type provide a noticeable increase in the bandwidth over which a transmitter may be adjusted for a conjugate match, but they have apparently not enjoyed much popularity. Perhaps it is because these antennas are considered somewhat unsightly. The antennas I'll discuss have wider bandwidths for the same level of complexity (and lack of beauty).

Antenna models

To provide a more convenient means of attacking the problems associated with broadband antennas, two types of antenna models were used to test the designs. Simple mathematical models were used to

By Terry Conboy, N6RY, 1231 Crestview Drive, San Carlos, California 94070
allow prediction of the approximate antenna impedance match vs frequency, before they were constructed, whenever possible. An equivalent circuit for a simple wire dipole appears in fig. 1. This model accounts for the change in reactance at the feedpoint as the frequency is changed, but it does not allow for the normal tendency of the resistive component of the feed impedance to rise with increasing frequency. This tends to be a second-order effect and doesn't seriously affect the results. It does, however, greatly simplify the calculations.

If the resonant frequency of this mathematical model is checked, it will be found to be 3742 kHz. It is not 3750 kHz, which is the arithmetic center of the band. Like all resonant circuits, the model exhibits geometric symmetry. The resulting effective center of the band is \( \sqrt{3500 \text{ kHz} \times 4000 \text{ kHz}} = 3742 \text{ kHz} \).

This frequency is used as the band center throughout the calculations to maintain band-edge symmetry when plotting the SWR. In real antennas, the many other variables involved make the 8-kHz distinction unimportant.

The plot of the calculated impedance for this mathematical model is shown on the Smith chart in fig. 2. The accompanying SWR plot is given in fig. 3.

This is typical of several antennas I have used in the past. These antennas were mostly inverted vees with center heights of about 12 meters (40 feet) and the ends about 3 meters (10 feet) high. A 5:1 SWR is considered intolerable by many Amateurs and much worse than a typical antenna would measure. This is probably because many SWR meters read closer to 3.5:1 for such an antenna. Close inspection with a noise bridge or other impedance-measuring equipment will show a typical SWR meter to be an incurable optimist. This defect is especially obvious when attempting to read fairly high mismatches at lower power levels.

Calculations of predicted antenna impedances and matches were facilitated by the use of programmable scientific calculators (HP-55 and TI-59) and an IBM 370 running the SPICE circuit analysis program written at the University of California, Berkeley. The antennas were also physically modeled by scaling them up in frequency and down in size by a factor of almost nineteen. This moves the resonant frequency to 70 MHz, which is the center of the i-f passband used in most microwave equipment designed for telecommunications service. Microwave link analyzers cover the range from 50 to 90 MHz and include the capability of accurately measuring return loss. Return loss is just 20 times the logarithm of the reflection coefficient, expressed in dB. Although the Hewlett-Packard 3702B/3710A and its companion return loss hybrid are designed for 75-ohm measurements, the use of a minimum-loss resistive matching pad permits its use with nominal 50-ohm loads. The loss of this pad was accounted for in the measurements made.

The scaled antennas were suspended from the ceiling inside a laboratory for the measurements. There were many reflections from the metal framework of the building, but they were probably on a par with those one could expect from power lines and the exteriors of buildings in the vicinity of an 80-meter antenna. All of the plots in this article show the equivalent scaled-down frequencies corresponding to the measurements made on the scale models. All of the necessary corrections have been made.

fig. 2. Calculated input impedance of the dipole equivalent circuit, normalized to 50 ohms.

fig. 3. Calculated SWR of the dipole equivalent circuit.
parallel antennas

This antenna configuration was suggested by the common use of paralleled dipoles for several bands. Others have apparently tried paralleling two antennas cut for different parts of the same band to widen the overall bandwidth with little success. The secret for proper operation is to mount the two antennas in such a way that they do not couple to each other. This can be done by mounting them at right angles as shown in Fig. 4.

One of the two dipoles is cut for 3530 kHz and the other to 3966 kHz. The higher frequency is 1.06 times the geometric center of the band (3742 kHz). The lower frequency is the center frequency divided by 1.06. The equivalent circuit of this arrangement is given in Fig. 5. It is just the parallel combination of two dipole equivalent circuits which have been adjusted up and down in frequency by multiplying and dividing the reactance values by the 1.06 factor.

It is recommended that this antenna, and the others shown as well, be fed through a balun. Currents flowing on the outer conductor (shield) of the coaxial feedline can cause undesired coupling between the antennas, which can restrict the bandwidth.

The calculated impedance of the antenna is shown in Fig. 6. The loop in the curve is interesting. The antenna impedance is capacitive at low frequencies just like the single dipole, crosses over through a perfect match, then becomes inductive. The impedance then becomes capacitive again as the frequency increases, goes through perfect match once again, and finally becomes inductive once more at the top of the band. The calculated SWR is shown by the solid line in Fig. 7. Measurements on the scale model of the antenna are also shown on the same plot by the dashed line. The measurements show good agreement with the calculations (most of the discrepancy between the two curves results from the individual dipoles never having a perfect match to 50 ohms). Despite this, the SWR is better than 2:1 across the entire band. If you can make dipoles that have a wider bandwidth than the ones assumed here, your antenna could be even better than this.

One of the interesting features of the parallel antenna is its tendency to be omnidirectional. Like the turnstile antenna, the currents in the two dipoles are out of phase. Over the middle of the band, at least, the currents in the two dipoles are roughly equal. Fig. 8 shows the calculated phase difference between the two dipoles as a function of frequency. The ratio of the two currents, given in dB, is plotted in Fig. 9. Even though the currents can differ by more than 10 dB at the band edges, the normal nulls in the

fig. 4. The parallel antenna is formed by two stagger-tuned dipoles, mounted at right angles to each other and fed at a common feedpoint.

fig. 5. Approximate equivalent circuit of the parallel antenna. Individual resonances are at 3530 and 3966 kHz.

fig. 6. Impedance calculated for the parallel antenna equivalent circuit, normalized to 50 ohms.

fig. 7. Calculated and measured SWR of the parallel antenna.
radiation pattern of a dipole will be filled to a large extent. Signals radiated at a high angle will be elliptically polarized. This is of some benefit when receiving. The antenna will respond fairly well to linearly polarized signals which arrive parallel to either antenna from high elevation angles. Since many of the signals received on the 80-meter band arrive at high angles, the elliptical polarization is probably of much more value than the omnidirectional characteristics observed toward the horizon.

It is worth noting what happens when the resonant frequencies of the two dipoles are separated by a different ratio. Calculations were made at two other pairs of resonant frequencies. When the ratio is 1.05 instead of 1.06, the SWR at the band edges is about 2.5 to 1 and the midband SWR is about 1.4 to 1. If the ratio is reduced to 1.04, the SWR at the middle of the band barely rises to 1.05 to 1, yet the SWR remains about 3.1 to 1 at the band edges. The loop in the impedance plot on the Smith chart shrinks, but it does not disappear until the two dipoles are tuned to the same frequency.

Most Amateurs probably don’t have a house lot of the right shape to permit placing two such antennas at right angles to each other. It may be desirable to erect the antennas as inverted vees instead of as conventional dipoles. Increasing the coupling between the antennas will reduce the bandwidth of the system, but the use of inverted vees has a minimal effect on the coupling. The angle between the dipoles may deviate from 90 degrees by about 15 degrees without significant degradation. If the angle decreases below 60 degrees, the match at the high end of the band will deteriorate. As the angle is decreased even more, the lower frequency antenna seems to dominate, and the tuning of the higher frequency dipole has less and less effect on system operation. When the antennas are nearly parallel, the SWR curve appears to be that of the lower frequency antenna alone.

**Wilkinson hybrids**

Before looking at the next antenna configuration, a discussion of a very interesting circuit is in order. The Wilkinson hybrid is very commonly used as a power divider or combiner at microwave frequencies. The arrangement of the circuit is shown in fig. 10. This is the simplest form of the circuit. Other variations allow driving more than two loads. Modifications providing very wide bandwidths have also been developed.

Fig. 11 shows the calculated impedance of a Wilkinson hybrid terminated with 50-ohm loads. The
fig. 12. Calculated SWR at the input of the Wilkinson hybrid using 75-ohm cables. Each leg was terminated in a 50-ohm resistive load.

quarter-wavelength lines are assumed to be 75 ohms instead of 70.7 ohms to indicate the performance to be expected with available cables. For this reason, the input impedance is never exactly 50 ohms. The corresponding SWR is shown in fig. 12.

Like other hybrid circuits, the Wilkinson provides isolation between the two loads. This occurs because a signal entering the Load 1 port can travel to the Load 2 port by two paths. One path is directly through the 100-ohm resistor; the other path is through one of the quarter-wavelength lines to the source and then back up the other quarter-wavelength line. Because the second path totals one half-wavelength, the signal traveling this route is 180 degrees out of phase with the signal through the resistor. As it happens, the amplitudes of the two signals are equal, and complete cancellation occurs.

No circuit is perfect, however, and several imperfections can cause a reduction in the isolation obtained between the two load ports. It should be obvious that the rejection is perfect only at the design frequency, since the transmission lines give the right phase shift only at that frequency. Even so, the isolation will be better than 20 dB over the whole 80-meter band. The other major source of less-than-ideal performance is the possibility that the driving source is other than 50 ohms. Most Amateurs fail to realize that the output impedance of a power amplifier designed to drive 50-ohm loads is seldom 50 ohms. This effect could easily cause a 10-dB degradation of the isolation between the output ports.

One clever use of the Wilkinson hybrid with Amateur antennas has been in driving phased vertical arrays. The isolation of the hybrid is useful in preventing interaction of the antennas via the phasing harness, which makes designing and adjusting such an array much easier.

Since the power from the input of the hybrid is equally split, the loss is 3 dB between the input and each output. Power coming in either of the two load ports is attenuated by 3 dB because half of the power goes back into the source port and the other half is dissipated in the 100-ohm balancing resistor. This has an interesting effect on the reflected power — it is cut in half! Unfortunately, when the reflected power is burned up in the load, it cannot be re-reflected and travel again out to the antenna or other load where the power is wanted. This causes a drop in system efficiency.

A special case occurs when two identical loads are driven by the hybrid: one load driven directly from the hybrid output and the other load driven through a quarter-wavelength of 50-ohm cable. If the loads are not 50 ohms, there will be a reflection at the load back toward the source. Since one of the loads is 90 degrees farther away, the reflection coming back will
be a total of 180 degrees out of phase with the reflection from the directly connected load. The reflected waves are thus equal and out of phase. The power summing action of the Wilkinson hybrid will cause them to cancel out. Where did the power go? It is all dissipated in the 100-ohm balancing resistor. None of the reflected power will arrive back at the source, and the apparent match is perfect. This leads directly to the next antenna system.

**turnstile plus Wilkinson**

A turnstile omnidirectional antenna is shown in fig. 13. The Wilkinson hybrid is used to drive the two antennas with equal power. An extra electrical quarter-wavelength of 50 ohm coax is connected between the hybrid and one of the antennas. The hybrid is made of two electrical quarter-wavelengths of 75-ohm coax and a high power noninductive 100-ohm resistor. The bandwidth of this antenna system is unbelievable! See fig. 14 for the calculated impedance of the system. The calculated and measured values of SWR appear in fig. 15. Many dummy loads don’t match this well. It is perhaps an apt comparison, unfortunately; the bad news is in fig. 16. This plot shows the equivalent loss as a function of frequency. At the edges of the 80-meter band, about 2.5 dB of transmitter output is turned to heat in the 100-ohm resistor. If your kilowatt power amplifier has 65 per cent efficiency, almost 285 watts must be dissipated at 3.5 or 4 MHz, leaving only 365 watts to be radiated.

These calculations are still based on the original dipole equivalent circuit with the 5:1 SWR at each band edge. The amount of loss in the resistor is reduced if the antennas fed by the hybrid are wide in bandwidth.

Baluns are almost mandatory for this antenna configuration. The cables in the phasing line and the hybrid will cause undesirable resonances to affect the impedances of the two dipoles if currents are allowed to flow on the cable sheaths. Whether a balun is used or not, the connections at the feedpoints must be insulated from each other. If no balun is used, this means the two shields of the coaxial cables at the feedpoints cannot be allowed to make contact, since these points are not at zero potential with respect to each other.

If a solid-state transmitter is in use and a transmatch is considered undesirable, an antenna of this type might be a good compromise. The power lost in the balancing resistor in the hybrid might be less than you would lose when the automatic drive reduction circuit is activated by another antenna with a poorer match.

**conventional turnstile**

An obvious question occurs immediately. Why not remove the 100-ohm resistor? This would transform the antenna into a conventional turnstile antenna. The Smith chart in fig. 17 shows what happens...
when this is done. The corresponding SWR curves are shown in fig. 18. The results are not that impressive, but are included here to satisfy possible curiosities. If the necessary space for all of the wire is available, a better choice would be the parallel antenna. This would eliminate all of the coaxial transformers and provide an increase in bandwidth.

**coaxial trap antenna**

When the wondrous claims about the “double bazooka” antenna came forth, it was hard to resist trying one. Even if only 10 per cent of the claims were true, it still had to be amazing. After the disillusion-ment,⁵ those strange lengths of RG-58/U cable cried for use in an antenna. The resulting design is sketched in fig. 19.

The shorted quarter-wavelength sections of coax look like parallel resonant traps that decouple the short end-sections at the high end of the band and make the antenna think it is shorter. At the lower end of the band, the shorted pieces of coax look inductive, slightly loading the antenna and allowing the antenna to be somewhat shorter physically than would otherwise be required. The larger diameter of the coaxial traps also contributes to the increased bandwidth.

The synthesis of a mathematical model for this antenna was not attempted. However, both full-size and scale models of the design were built. The full-size antenna used RG-58/U and the scale model used RG-174/U, a miniature 50-ohm coax. The scaling of the conductor diameters is not in proportion to the frequency ratio, which certainly results in some errors.

A Boonton model 250-A RX meter was used through a known length of 50-ohm cable to measure the impedance of the scale model. The scaled down frequencies and impedances are plotted in fig. 20. The equivalent SWR curve is shown in fig. 21. Notice that the shape of both plots is similar to those of the previously mentioned parallel antenna, although the overall match is not as good. This antenna is worth consideration when the necessary acreage is not available for two full-size dipoles.

Tuning the coaxial trap antenna can be difficult. The first thing to do is to grid-dip the traps as shorted half-wavelength sections at about 7.6 MHz. A noise bridge could be used to look for a zero impedance at this frequency instead. When this is done, the traps will be quarter-wavelength at about 3.8 MHz. If a noise bridge or grid-dipper is not available, cutting to the specified length shown may be close enough.

If the coaxial cable used for the traps has foam-polyethylene insulation, the traps must be lengthened to approximately 15.85 meters (52 feet) and the inner wires shortened to about 1.4 meters (4 feet, 7 inches). For Teflon-insulated cables, the appropriate dimensions are 13.75 meters (45 feet, 1 inch) and 3.5 meters (11 feet, 6 inches).

---

⁵ Boonton model 250-A RX meter was used for measurements.

---

fig. 18. Calculated and measured SWR of the conventional turnstile antenna.

fig. 19. Diagram of the coaxial trap antenna. The traps resonate at approximately 3800 kHz.

fig. 20. Measured impedance of the scale model of the coaxial trap antenna normalized to 50 ohms. Frequencies are scaled down to 80-meter equivalents.
Once the coaxial traps are cut, connect the wires to them that go from the shorted end of the traps to the feedpoint. Leave these pieces of wire about 30 cm (1 foot) longer than indicated to allow for trimming. Hoist the antenna into position without the end wire stubs connected. Adjust the length of the inner wire sections to obtain resonance around 3800 kHz. Then connect the end stubs to the center conductor at the open-circuited end of the coaxial traps. Trim their length to optimize the match at the low end of the band.

It may be necessary to go back and make minor adjustments to the lengths of the wires at both ends of the coaxial traps to center the SWR curve as desired. Remember to keep the lengths of all sections the same on both sides of the antenna. It is quite possible that your dimensions may come out quite different from those shown, due to effects from the surroundings.

**comments please**

I hope that some of the ideas presented here have been thought provoking. I would be interested in hearing of any productive modifications to the designs presented in this article. Comments on both successes and failures in working with these antennas are also welcome.

(813) 823-1032
Matching problems in VHF coax systems can be a stumbling block for the Amateur interested in advanced or large-scale antenna arrays. Commercial antennas match closely to a 50-ohm system and provide little challenge. When several antennas are stacked, however, the matching or feed system becomes more complex. If the antenna is homebrew, even one antenna can cause matching problems by providing other than a 50-ohm nonreactive load.

There are two simple methods of matching a 50-ohm system to a load of another impedance: the quarter-wavelength transformer section and the matching stub. Each method has its good and bad points; each is perfect for some applications and much less than perfect for others.

The quarter-wavelength transformer section is well described; it is simply a quarter-wavelength section of coaxial cable used between the load and the rest of the feedline. The Zo, or characteristic impedance, of this section is an interim value between the load and the feedline impedances. It is this impedance value and the quarter wavelength that are critical to proper transformer function. Since the formula for transformer section Zo requires the desired impedance at both ends of the section, these values must be known.

The stubbing method involves a physically short, open-circuited section of coaxial cable connected into the feed line with a T connector (see fig. 1). The

By Jim Pruitt, WB7AUL, 8505 N.W. 91st Street, Oklahoma City, Oklahoma 73132
positioning piece places the stub at a point on the line where the resistive component of the impedance is equal to $Z_0$ and the reactive component is inductive. The stub itself is simply a capacitor which is adjusted to cancel the inductance. This makes the stub attachment point appear to be resistive and equal to $Z_0$; in effect, it becomes a perfect load. To use a stub assembly you must know the following:

1. VSWR of the unstubbed system (measured at the antenna)
2. Wavelength in the line
3. Actual position of the standing wave voltage minimum point nearest the load

**which system?**

The strong points of the systems dictate their best uses. When the load impedance is unknown (and probably complex), the stub is the easiest choice. When paralleling antennas of known impedance, the quarter-wavelength section is perfect for the impedance conversion, since the impedance values for both the antenna and transmission line are known. If multiple homebrew antennas are used, of course, each antenna is stubbed to 50-ohms and paralleled with quarter-wavelength sections.

In general terms, however, unknown complex impedances can easily be reduced to a purely resistive load which is equal to the feedline $Z_0$ with a stub, while transformations from one known impedance to another are more easily done with transformer sections because the construction is easier.

**stub system**

When using a stub matching system, I use a capacitive stub because the end of the stub is left electrically open. This allows easy adjustment of length and permits the whole feed system to be checked occasionally with a leakage meter to check dielectric condition.

The stub is installed in the inductive region of the feedline at a point within 90 degrees toward the generator from the voltage minimum nearest the load (see fig. 2). The distance from the load to the first voltage minimum point is part A of the positioning piece length and should be found by direct measurement. A slotted line may be used if its velocity constant is identical to that of the cable in use. Details of its use may be found in reference 1.

If an appropriate slotted line can’t be found, a simple fluted line may be constructed from a 60-cm (2-foot) length of coaxial cable. The cable is marked every 2.5 cm (1 inch). A small (1-cm, or 3/8-inch)
To convert \( \theta \) in electrical degrees into part B in cm, first measure the distance between the voltage minimum points on your fluted line. Multiply this figure by two to find the line wavelength. Then

\[
\text{part B (cm)} = \frac{\theta \times \text{line wavelength (in cm)}}{360} \quad (2)
\]

If you're working with inch dimensions, simply substitute those dimensions at the appropriate places in the above formula.

Line wavelength can also be calculated from

\[
\text{Line wavelength} = \frac{29980 v_p}{f_{\text{MHz}}} \left( \text{cm} \right) = \frac{11803 v_p}{f_{\text{MHz}}} \left( \text{inches} \right)
\]

where

- \( v_p \) = velocity factor of the line (0.686 is typical for coax with polyethylene dielectric)
- \( f_{\text{MHz}} \) = operating frequency
- part B = the distance from the voltage minimum to the stub location
- VSWR = the standing wave ratio of the unstubbed system measured at the antenna
- \( \theta \) = part B expressed in electrical degrees
- Line = wavelength measured on the fluted line in cm (or inches) or computed.

The total length of the positioning piece is part A (the measured part) plus part B (the computed part). A section of feedline cut to that length (including connectors) is connected as shown in fig. 4 with a variable capacitor substituted for the stub.

As the capacitor is adjusted, the reverse power indicated on a VSWR meter will dip to a minimum. If the positioning piece is the correct length, the minimum will be zero. If you don’t obtain a zero reading, loosen the connector on the stub end of the positioning piece as shown in fig. 4 to slightly lengthen the piece (don’t take it off). If the reflected power dimin-
We've Been Taking Notes.

Combining your ideas with some of our own, we've come up with what has to be the most advanced and convenient terminal available. These are some of the conveniences you can now enjoy by putting the DS3100 ASR in your RTTY and CW station:

**ASR Operation (Compose your transmission **WHILE** receiving)**

- 150-line Receiver Buffer
- 50-line Transmit Buffer
- Split Screen to Show Buffers
- Internal Real-Time Clock
- 10 Programmable Messages
- Automatic Answer-Back (WRU)
- Morse, Baudot, or ASCII Operation
- RTTY and CW identification
- Full 128-Character ASCII
- 110-9600 baud ASCII
- 60-130 WPM Baudot
- 1-175 WPM Morse

Write or call for the DS3100 ASR specifications and see how YOU have helped design the new standard in amateur radio terminals.

I.E.C. Interlco, Biarco
ishes as the connector is loosened, the positioning piece is too short and should be lengthened in 1-cm (3/8-inch) increments until a minimum is obtained (representing a VSWR of 1.1 or less). If loosening the connector increases the reflected power, the piece is too long and should be shortened in 1-cm (3/8-inch) increments.

When the positioning piece is the correct length, the minimum reflected power should be noted and an open-circuited coaxial stub with a connector on only one end should be substituted for the capacitor box. The stub length in electrical degrees is determined with the following formula

$$\phi = \tan^{-1} \frac{\text{VSWR} - 1}{\sqrt{\text{VSWR}}}$$

where

$$\phi = \text{electrical length of the stub in degrees}$$

This is converted to stub length in cm by this formula:

$$\text{stub length} = \frac{\phi}{\text{line wavelength, cm}} \times 360$$

The stub should be cut at least 2.5 cm (1 inch) too long. After it is in place use garden pruning shears to cut off first 1 cm sections, then smaller ones as the reflected power approaches the previously noted minimum; try not to cut off one section too many!

When the stub is properly installed and pruned, your antenna will show a virtually perfect 50-ohm load to the feed system and the VSWR on the feed-line will be nearly 1:1.

![Sample section of a homemade fluted line.](image)

### quarter-wavelength matching system

When using a quarter-wavelength transformer section there are only two computations to make. First the quarter-wavelength length is found either by direct measurement with a fluted or slotted line section or by the following formula

$$\text{transformer section length} = \frac{29980 \mu \text{b}}{4f_{\text{MHz}}} \times \frac{1}{\text{inches}}$$

Next, the characteristic impedance of the transformer section is determined from

$$Z_0 = \sqrt{Z_s \cdot Z_r}$$

where

$$Z_0 = \text{impedance of the matching section}$$

$$Z_s = \text{impedance at one end of section}$$

$$Z_r = \text{impedance at the other end of the section}$$

A section of the appropriate cable is then chosen, cut to the computed length, equipped with connectors, and installed in the system (see fig. 5).

The real problem with this method is finding the appropriate impedance cable, of course. Referring to the example, how far would you have to look to find commercial 61-ohm cable? The problem can be alleviated if the system is designed so the required characteristic impedance is near commercially available

![Example of a quarter-wavelength matching transformer.](image)
160 Meter Enthusiasts...

Has Drake got a SECRET WEAPON for you!

**DRAKE MN-2700, THE 2kW ANTENNA MATCHING NETWORK**

With its truly unique antenna feed switching design, the MN-2700 is an instrument that will completely change the mode of a balanced-line fed 135 foot doublet to a special configuration that provides very effective 160 meter performance. And best of all, it’s done with the simple flip of a switch on the front panel.

Consider a typical all-band antenna set-up — a 135 foot doublet, center-fed with 60 to 70 feet of balanced line at a height of 45 to 60 feet. The Drake MN-2700/B-1000 will match this as a true balanced system on 80 thru 10 meters.

But what about 160 meters? Many amateurs recommend tying the feeders together and using the antenna as a vertical with a “top-hat”. In fact, we suggest this ourselves in our manual.

However, the use of this or any vertical assumes you have a good ground or radial system for efficient operation. If you do not have enough room or do not wish to install such a radial system, performance may suffer. And if you do have radials, you still have to change the feeder connections each time you operate on 160 meters.

On the other hand, when you use the MN-2700/B-1000, simply leave the feeders in the balanced connection as you would for 80 thru 10, and move the special antenna selector switch to Position No. 4. This automatically converts half of the antenna and feedline to an inverted “L”, fed through a 4:1 impedance transformer, with the other half operating as a counterpoise.

This system offers the convenience of “stay in your chair” operation, while providing an effective means of working 160 meters with a relatively small antenna.

The Drake MN-7 offers the same special switching design, and is rated for 250 watts output.

**Memo from Drake**
values, but this isn’t always possible. You can also construct the cable yourself in rigid form, or forget it.

**quarter-wavelength sections as power dividers**

If careful attention is paid to the values of impedance available for conversion at different points in a proposed antenna system, some natural combinations can be found. One example is the parallel combination of 50-ohm antennas with 75-ohm matching sections as shown in fig. 6.

In this example 50-ohm loads are connected to 71-ohm matching sections which transform the impedance to 100 ohms. The feedline then sees two 100-ohm loads in parallel, or a total load impedance of 50 ohms. In addition, since the input points to the 100-ohm section are equal, the current (and power) will split evenly between the antennas.

Further, loads with the same impedance can be fed with different power levels by using different cable values in the sections (although this brings back the problem of noncommercial impedance values). In this case the desired power levels are converted to currents. The input impedances to the transformer sections are then selected to obtain the desired currents as shown in fig. 7.

**phasing**

Another factor to remember when operating multiple antennas is phasing, or timing the arrival of rf energy at each antenna. Generally, if the antennas are simply stacked together, you want them to operate in phase; all feedlines from the antennas to the matching transformers must be equal length.

If the antennas are not to be in phase, the appropriate delays can be easily obtained by adding additional cable in the indicated antenna feedlines. Added cable length increases the phase delay; the amount of delay can be computed from

\[
\text{degrees of delay per cm of cable} = \frac{360}{\text{line wavelength, cm}}
\]

Stubbing and matching sections are not really the bugaboo that they may seem. A good stubbing job can be done easily in an hour; a matching transformer takes less time. The frequency changes over the two-meter band, for example, have negligible effect. These matching tricks can be a big help in making efficient, custom-tailored Amateur arrays.

Don't forget the WV-1 for the best in vertical needs.  
The WV-1 is the 10-40m Antenna you should consider!

ACT NOW!  
Buy the WV-1 and Wilson will treat you to the Radial Kit ...FREE of charge!

WV-1 SPECIFICATIONS:
- Input impedance: 50 ohms
- Power handling capability:
  - Legal limit: Two High-Q traps with large diameter coils
  - Low angle radiation omnidirectional performance
  - Taper swaged aluminum tubing
  - Automatic bandswitching
  - Mast bracket furnished
  - SWR: 1.1:1 on all bands
  - O.D. heavy wall aluminum tubing
  - Does not require guyng
  - Overall length: 19' 8".

The TT-45 is a freestanding tower. Ideal for installations where guys cannot be used. If the tower is not being supported against the house, the proper base fixture accessory must be selected.

Phone (702) 739-1931 • Telex 684-522

Wilson Electronics announces a factory authorized rebate program.

Here's how it works:

Purchase a TT-45 and a System Three at the same time and Wilson will give you a factory 5% rebate from the price you paid for the package. You can use this to pay for the concrete to install it, or buy the XYL a little something to keep her happy! Or we will give you, at no charge, a M-27, the best 7 element, 2M beam available today! The choice is yours to make!

Just send Wilson the receipt of your purchase from your dealer, showing your cost, and let us know what you want — 5% cash, or a M-27. But hurry! This offer expires midnight, May 31, 1979, and receipt must be mailed before July 1, 1979.

Don't wait! See your nearest dealer to take advantage of this great Give-A-Way!

SPECIFICATIONS

TT-45 TOWER
- Maximum height, 45'
- 800 lbs. winch with padlock feature
- 2800 lb. raising cable
- Totally freestanding with proper base
- Total weight, 193 lbs.

Recommended accessories:
- RBRF-10, SBRF-10,CBRF-10.
The TS-820S... known worldwide as the Pacesetter. Amateur Radio Operators universally respect its superb quality, proven through thousands of hours of operating time under all environmental conditions. The TS-820S has every feature any Amateur could desire for operating enjoyment, on any band from 160 through all of 10 meters.

**TS-820S**

You can always tell who's running a TS-820S. Its superb quality stands out from all the other rigs on the band... and when the QRM gets heavy, the TS-820S's adjustable RF speech processor, utilizing a 455-kHz circuit to provide quick-time-constant compression, will get the message through. RF negative feedback is applied from the final to the driver to improve linearity, and third-order products are at least —35 dB. Harmonic spurious emissions are less than —40 dB and other spurs are less than —60 dB. RF input power is 200 W PEP on SSB, 160 W DC on CW, and 100 W DC on FSK. Receiver sensitivity is better than 0.25 \( \mu \text{V} \) for 10 dB S/N. The TS-820S is known for its superb receiver selectivity, and its famous IF shift easily eliminates heavy QRM. That's why the TS-820S is the DXer's choice.

See your local Authorized Kenwood Dealer today.

Kenwood's unbeatable combination. The VFO-820 solid state remote VFO adds greatly to the versatility of your TS-820S. It has its own RIT circuit and control switch and is a perfectly matched accessory. The SP-820 deluxe external matching speaker includes audio filters for added versatility on receive and two audio inputs.

multi-band antenna system

A different approach to triband-beam design results in performance comparable to that of large, single-band, multielement Yagis.

Until the early 1950s, a person interested in serious DX had to resort to stacked Yagis, fittingly called a Christmas tree, when faced with the limitation of a single rotor and mast. For most of us, however, it is difficult enough to build and tune a single Yagi beam, much less three stacked beams. During the record sunspot peak of 1956-58, several Amateurs tried to solve the multiband antenna problem, resulting in a number of new beams, especially mini types.

Most people are familiar with the W3DZZ-trap antenna either as a dipole, ground plane, or Yagi tribander. The disadvantages and difficulties of this antenna, compared with a single-band, full-size Yagi, are that at 14 and 21 MHz the element is less than full size, causing reduced gain and bandwidth (both SWR and F/B ratio bandwidth). It is a major problem to seal the traps (tuned circuits) so that moisture and the polluted atmosphere do not cause corrosion at element, coil, and capacitor contacts, especially if dissimilar metals are used. In addition, a compromise between trap Q and bandwidth had to be chosen. For a triband element, four traps are required per element, with the contact resistance in the traps causing losses. This form of the triband Yagi is now the most widely used Amateur DX antenna, and it is manufactured in several countries.

G4ZU tribanding

Substantial initial interest, except in the U.S., earned G4ZU British patent number 790,576 (12-2-1958) for his multibanding method. Here are some claims and rebuttals for his version:

1. A beam element that was self-resonated near 21 MHz was made to resonate near 14 MHz by inserting a loading coil or twin boom hairpin loop in the middle of the element.

Fact. The coil actually used had only about half the inductance a coil would need to act as claimed.

2. An “automatic-switching stub” in the form of a piece of open-ended twin lead or coaxial cable was connected in parallel with the loading coil. The stub was to act as an electrical short when the antenna was used near 21 MHz. This was because the stub alone resonated at this frequency, electrically eliminating the tuning effect of the loading coil at 21 MHz.

Fact. An open quarter-wavelength stub acts, under matched conditions, like a near short, but G4ZU had a different case and insisted that the stub cable had to have a very special “velocity factor” (i.e., capacitance per unit of length). It appeared to me that the cable capacitance, in conjunction with the parallel inductor, performed the two-band tuning — and not the stub, as claimed.

3. The 28-MHz tuning was riot explained by G4ZU. In private correspondence, the inventor stated that the coil-to-mounting-channel capacitance did the trick together with a part of the stub.

Fact. By placing the stub cable inside the element or double-boom tubing, the resultant coupling of distributed L and C caused the 28-MHz resonance to occur, along with others.

The experiments which demonstrate these facts can easily be repeated. Start with a dipole resonating at

$$f_{3rd} = \frac{300}{\lambda\text{(meters)}} \text{ or } \frac{492}{\lambda\text{(feet)}}$$

A dipole can be tuned to a lower frequency by inserting a loading inductance, L.

By Hans F. Ruckert, VK2AOU, 25 Berrille Road, Beverly Hills, 2209 Australia

This article first appeared in *Amateur Radio*, the journal of The Wireless Institute of Australia, in April, 1978.
Or, to a higher frequency with a capacitance, C.

By looking at the distributed L and C components, the antenna can be reduced to a parallel-tuned circuit,

with the dipole itself acting as a series-tuned circuit,

resulting in the combination looking like two resonant circuits.

The paralleled parallel-(L_p + C_p) and series-tuned circuits (L_s + L_b) form the "multiband tank" used in transmitters to cover 3.5 to 30 MHz without coil switching. There are always two resonances occurring at the same time, 3.5 to 8 MHz (L_p and C_p) and 7 to 30 MHz (L_s and C_s), depending on the values of C_p and C_s.

By replacing the series-tuned circuit (L_s and C_s) with the dipole half-elements, and the cable capacitance by a lumped capacitor of the same value, you obtain (in either case) a two-band element (for example 14 and 21 MHz, 21 and 28 MHz, or even 70 and 180 MHz). The cable (stub) resonance and the velocity factor of the cable used are of no consequence — only the cable capacitance matters. L_p may be a coil, a hairpin loop, or a double boom with shortening bar. Bringing the cable (C_p) near the element creates more resonances, due to the distributed L.

This form was too difficult to tune, and unwanted resonances occurred as well.

After understanding what made the G4ZU beam work on three bands, I looked for a three-frequency circuit that was tunable (and controllable) and could be converted into a triband antenna element. To obtain resonance on three different frequencies (14.15, 21.25, and 28.6 MHz) at the same time without switching inductors or changing capacitors, you need three inductors and three capacitors arranged as follows:

As previously described, one series-tuned circuit can again be replaced by a dipole to obtain a triband element. In A above, you then have two differently tuned, parallel-tuned circuits in series; in B, a series and a differently tuned parallel-circuit in parallel in the middle of the element. This "triband element" may be any Yagi-type radiator, director, or reflector, the groundplane radiator, or a cubical quad element.
The dipole may have any length, from one quarter wavelength to a full wavelength. The resonant circuits are not tuned to the antenna operating frequencies, and should not be confused with dipole traps (W3DZZ type).

Since 1960, the A version has been built in Yagi, groundplane, and quad form by Amateurs in several countries. I’ve described these antennas in VK, ZL, DL and W-land Amateur literature. Other Amateurs (JA, ZS, DM, OK) have also described their experiences with this system. Unfortunately, antenna manufacturers showed no interest. This is a true tri-band antenna element, where the full element is used on all three frequency bands, unlike the unused dipole ends of the W3DZZ system.

**DJ2UT version**

DJ2UT was particularly successful in using this tri-band-tuning system, and he asked the writer for permission to produce this antenna and to call it the VK2AOU beam (see fig. 1). He had continued the antenna’s development, later extending the 14-MHz elements to full size to be competitive with other full-size Yagis. On 21 MHz, the element is 0.75 wavelength and on 28 MHz a full wavelength long (collinear), resulting in excellent gain and bandwidth on the 15- and 10-meter bands. The front-to-back ratio, and so the reflector gain and bandwidth, were improved by feeding the reflector via a crossed-phasing line. This resulted in more concentrated radiation in the vertical plane. Mechanically, the reflector to driven element and driven element to director spacing is only 2 meters (6 feet), producing a short beam. For strength, a twin boom (25 x 3 mm [1 x 1/8 inch] Al-Mg-Si corrosion-resisting tubing) is used. All clamps are cast from an aluminum alloy. Only stainless-steel screws, bolts, and nuts are used, to avoid electrolysis and corrosion at contacts between dissimilar metals.

**feed system**

Feeding with a single coaxial cable presented a number of problems because of the large impedance and phase changes, especially at 21 MHz. A T-match connected to both the driven element and reflector finally gave the desired, and easy to control, results. The 28-MHz match is improved by selecting a suitable L/C ratio for the tuned circuits. By placing proximity, or matching elements, for 21 MHz and 28 MHz in front of and near the driven element, the impedance at the T-match is also suitable for 21- and 28-MHz operation. At 21 MHz, the resonant frequencies of the 21-MHz match element and the radiator are above and below 21.25 MHz respectively, much like a band filter. At 28 MHz, the match element also acts like an additional director.

**construction**

The centers of the long elements and the 21-MHz match element have a polycarbonate center that seals and holds the coaxial cable capacitors (about 75

---

**fig. 1.** Physical layout of the VK2AOU multiband beam as manufactured by DJ2UT. The capacitors are formed by short lengths of coax inserted in the center of the element, while the inductances are small hairpin loops.
Fig. 2. Performance characteristics of the VK2AOU beam. The test dipole was located at the same height, though ten wavelengths distant.

The antenna can handle a continuous RF power of 2.5 kW. The tuning elements are not at high RF voltage points as in trap beams. Galvanized copper solder lugs are used to attach the RG8U coax. The use of the popular 1:1 ferrite balun is not recommended for obtaining symmetrical feeding of the beam halves because it was discovered that the same degree of coupling was achieved without this core. DJ2UT recommends using 3.5 meters (11.5 feet) of coaxial cable in the form of a closely wound, six-turn cylindrical coil near the beam feed point to achieve a balanced feed.

Performance

When compared with a W3DZZ-type triband beam on a 7-8 meter boom, this antenna exhibits a superior forward gain and reflector bandwidth (see fig. 2). On 20 meters, the performance is better than that of a two-element quad or three-element, full-size Yagi. On 15 meters, due to the extended elements, performance is similar to that of a four-element, full-size Yagi. On 10 meters the performance is due to the collinear (double length) elements and the 10-meter match element, and is comparable to the performance of a five- or six-element Yagi.

The VSWR curves are shown as a band because nearby objects cause a change depending upon proximity.

Bibliography

The age of tone control has come to Amateur Radio. What better way to utilize our ever diminishing resource of frequency spectrum? Sub-audible tone control allows several repeaters to share the same channel with minimal geographic separation. It allows protection from intermod and interference for repeaters, remote base stations, and autopatches. It even allows silent monitoring of our crowded simplex channels.

We make the most reliable and complete line of tone products available. All are totally immune to RF, use plug-in, field replaceable, frequency determining elements for low cost and the most accurate and stable frequency control possible. Our impeccable 1 day delivery is unmatched in the industry and you are protected by a full 1 year warranty when our products are returned to the factory for repair. Isn’t it time for you to get into the New Age of tone control?
OF A NEW AGE.

**TS-1** Sub-Audible Encoder-Decoder • Microminiature in size. 1.25” x 2.0” x .65” • Encodes and decodes simultaneously • $59.95 complete with K-1 element.

**TS-1JR** Sub-Audible Encoder-Decoder • Microminiature version of the TS-1 measuring just 1.0” x 1.25” x .65”, for handheld units • $79.95 complete with K-1 element.

**ME-3** Sub-Audible Encoder • Microminiature in size, measures .45” x 1.1” x .6” • Instant start-up • $29.95 complete with K-1 element.

**TE-8** Eight-Tone Sub-Audible Encoder • Measures 2.6” x 2.0” x .7” • Frequency selection made by either a pull to ground or to supply • $39.95 with 8 K-1 elements.

**PE-2** Two-Tone Sequential Encoder for paging • Two call unit • Measures 1.25” x 2.0” x .65” • $49.95 with 2K-2 elements.

**SD-1** Two-Tone Sequential Decoder • Frequency range is 268.5 - 2094 Hz • Measures 1.2” x 1.67” x .65” • Momentary output for horn relay, latched output for call light and receiver muting built-in • $59.95 with 2 K-2 elements.

**TE-12** Twelve-Tone Sub-Audible or Burst-Tone Encoder • Frequency range is 67.0 - 263.0 Hz sub-audible or 1650 - 4200 Hz burst-tone • Measures 4.25” x 2.5” x 1.5” • $79.95 with 12 K-1 elements.

**ST-1** Burst-Tone Encoder • Measures .95” x .5” x .5” plus K-1 measurements • Frequency range is 1650 - 4200 Hz • $29.95 with K-1 element.

**COMMUNICATIONS SPECIALISTS**
426 West Santa Avenue, Orange, CA 92667
(800) 854-0547, California residents use: (714) 996-3021
There's no doubt that the Citizen-Band boom is here. There are millions of CBers and millions more CB radios and accessories. Hams, always ready to make something out of nothing, are discovering many ways to use CB components for Amateur-Radio use. This article is about another use: a 2-meter, ¼-wavelength, mobile gutter-clip antenna made from CB antenna parts. Although I designed it for 2 meters, the same techniques could be used for any vhf or uhf band by making appropriate changes in antenna length for the desired frequency.

Starting at the base and working up, the parts used are these: a gutter-clip antenna mount (originally intended for use with a center-loaded CB antenna); a spring with an M6 (¼-20) threaded female base and a top that takes a whip (this is a part from a base-loaded CB antenna); and, finally, the whip itself, which is stainless steel. The whip can be a CB or Amateur Radio part.

construction

Here's how it all goes together. The gutter-clip mount that I found had RG-58/U coax and a PL-259 connector attached. If the clamp you find doesn’t include the cable you’ll have to make one. Obtain a 3-meter (10-foot) length of RG-58/U coax and solder a PL-259 connector (or the connector to fit your radio) to one end.

The other end of the coax goes to the antenna. Solder the coax center conductor to a solder lug large enough for a 6.4-mm (0.25-inch) bolt. Even if your clamp has coax with it, you may have to replace the solder lug with one that will fit. If you solder on a new lug, use heat-shrink tubing over the connection, part of the lug, and about 25 mm (1 inch) of the coax. This will help protect the connection and act as a cable strain relief.

Connect the coax outer conductor to the metal clamp. This is a little tricky. Make the ground connection at the U-shaped holdown clamp. To do this and still have shielding from there to the antenna base, carefully cut away a 3-mm (0.125-inch) piece of the outer insulation all the way around at the point where the coax will be under the holdown clamp. Be careful not to cut the braid. Then wrap a 25-mm (1-inch) length of bare wire around the coax braid. This wrap will protrude past the outer insulation to provide good contact with the clamp and bracket when tightened down.

You're now ready for the spring. The spring may have a 6.4-mm (0.25-inch) stud screwed into the bot-
tom; if so, remove the stud. To attach the spring to the clamp, use an M6 (1/4-20) by 25-mm (1-inch) round head bolt through the solder lug, an insulating washer, the clamp, an insulating washer, a lock washer, and the bottom of the spring in that order, bottom to top. Note that some of the gutter clamps have insulating washers smaller than 6.4 mm (0.25 inch); if so, drill them out before assembling. Tighten the bolt.

radiating element

You’re now ready for the antenna whip. It can be almost any stiff wire, but stainless steel designed for this purpose looks good and won’t rust. You may be able to find a broken piece large enough to work, or it can be purchased at any electronics store that sells CB or ham equipment. A CB whip for a bottom-loaded antenna can be used and should be long enough to make two 2-meter antenna whips.

The whip goes into the top of the spring and is held in place with a setscrew (which may take a hex key wrench for adjustment). Position the whip in the opening as far as it will go, then back it out about 12.7 mm (0.5 inch). In this way you can loosen the setscrew and make minor changes in whip length without having to cut the whip. Antenna length is measured from the top of the whip to the bottom of the lockwasher under the spring. How do you find the correct length? Use the following formula:

\[ \text{length in mm} = \frac{74970}{\text{frequency in MHz}} \]

\[ \text{length in inches} = \frac{2952}{\text{frequency in MHz}} \]

For example, the middle of the 2-meter repeater band is 147 MHz:

\[ \text{length in mm} = \frac{74970}{147} = 510 \]

\[ \text{length in inches} = \frac{2952}{147} = 20 \]

operation

After the antenna is cut to the correct length you’re ready to try it out. Clamp it on to the gutter mount and feed the coax through a window. A vhf swr bridge can be used to adjust the whip length for the lowest reflected power. This shouldn’t be necessary, however, if you calculated and measured accurately.

In using the antenna, I found it to be very effective and convenient. Its performance is more than adequate for repeater use, and it’s easy to unclip and slip through the car window when the car is parked, which is an excellent security feature. The antenna is small and weighs much less than the CB antenna for which the gutter clamp was intended, so you should have no problems with the clamp coming loose.

My total cost came to around $4 for parts, which were purchased from a “junk box” at a local Olson electronics store. Antenna parts from damaged CB antennas or surplus parts should be available free or inexpensively from a CBer friend or a CB store. Even if the parts are purchased brand new, the cost is still considerably less than for most commercially made units.
sloping antenna array
for 80-meter DX

An array using wire elements that has given a good account of itself during the pileups — it's the W2LU sloper.

Anyone who has put in an evening trying to work DX on 80 meters will understand the frustration that results in a desire to develop a better antenna system for this band. With 80-meter DX you soon learn that the criteria by which a “better” antenna system is judged would weigh directivity nearly equal to gain: i.e., “You can’t work ‘em if you can’t hear ‘em.”

An increasingly popular way of obtaining a reasonable amount of both has been with the sloping dipole system. The sloper, as must be expected, has both positive and negative aspects.

the sloper antenna

Probably the sloper’s biggest drawback is that, to get good azimuth coverage, it’s necessary to have at least two radiators directed 180 degrees apart, with three radiators at 120-degree intervals being preferable. This arrangement requires a good-sized piece of real estate, typically a 61 by 53 meter (200 by 175 foot) lot for a full three-radiator system with reflectors.

The second drawback is that a big tower is highly desirable. Although functional slopers have been erected with tower heights of only 15 meters (50 feet), heights of 24 meters (80 feet) or more are preferable, with 31-37 meters (100-120 feet) being ideal.

On the positive side we have a number of points. Perhaps first is the sloper’s excellent operating characteristics. The complete system as outlined in this article demonstrates a front-to-back ratio of 20-25 dB on signal paths on the order of 3200 km (2000 miles) or more. The gain of the system is estimated to be between 2 and 5 dB over a dipole, depending on the direction relative to the radiator.

fig. 1. Plan view of the experimental sloper antenna. Two sloping dipoles were used. One was pointed directly at a vertically polarized test signal; the second was pointed 180 degrees away.

The other major advantage of the system, once the cost of the real estate and tower have been discounted, is its basic simplicity and its cost and effort effectiveness. The radiators are ordinary dipoles, and the reflectors are either plain wire or inductively loaded wires. Furthermore, the radiators, being dipoles, present approximately balanced feedpoints and don’t require an extensive ground system for efficient operation. A system of radials tied in with a grounded tower would probably reduce ground reflection losses.

By Eugene B. Fuller, W2LU, 1185 Wall Road, Webster, New York 14580
experimental system

While developing this system, I performed experiments to determine the ideal angular spacing between the radiators and radial reflectors. The configuration used for these experiments consisted of two slopers; one was pointed directly at a vertically polarized test signal source approximately 0.8 km (0.5 mile away, and a second was pointed 180 degrees away. Two reflector wires were then placed radially, one to each side, so that the included angles between the radiators and reflectors could be varied in a symmetrical fashion as shown in fig. 1.

The tests were repeated several times and the results appeared to be consistent. Table 1 indicates representative values.

Several conclusions were drawn from these tests. First, by comparing signals from the two dipoles, I found that an included angle of 60 degrees between the reflectors and the further dipole represented the best front-to-back ratio — 20 dB. An angle much smaller than this resulted in degradation. An angle of 60 degrees between the reflectors and the near dipole resulted in a forward gain of about 5 dB over a dipole. Therefore a system of three dipoles and three reflectors optimized both front-to-back ratio and forward gain. A four-dipole, four-reflector system would probably perform satisfactorily; however it's doubtful whether the added complexity would produce meaningful improvement in performance. On the other hand, dropping back to a two-dipole, two-reflector system would definitely result in degraded performance.

A system was then installed using a three-dipole, three-reflector configuration with 60-degree spacing as shown in fig. 2. All reflectors were cut to 43 meters (140 feet) and all dipoles were made resonant at 3.8 MHz. Although direct 180-degree, front-to-back checks were no longer possible, a large number of on-the-air checks confirmed the expected results.

As a further refinement to the system, I decided to try adding additional parallel reflectors under each dipole as shown in fig. 3. In this installation the dipole and radial reflectors are supported by a 30.5-meter (100-foot) tower. The added reflectors were hung from the 21-meter (70-foot) point on the tower, resulting in approximately 0.1-wavelength spacing from the dipole. Each reflector was 26 meters (85 feet) long and resonated at 3.5 MHz, with about 30 turns of B&W 3905-1 inductance. Obviously, higher towers would allow one to take greater advantage of this concept by making possible greater spacing and less inductive loading. Although I made no direct comparative measurements with and without these reflectors, it seemed that front-to-back ratio improved by about 5 dB, and the theory seemed valid.

Tuning of the parallel reflectors was accomplished by grid dipping and noting the amount of rf energy in the element. With power fed to the radiator, I could...

**Fig. 4.** Beam pattern of the sloper using three radiators, three radially oriented reflectors, and three parallel reflectors. The data indicates response in the horizontal plane; that is, directivity, not gain.

draw an arc with a pencil from the low end of the reflector.* I assumed that this arcing was greatest when the element was self-resonant. The element was then made to resonate about 10 per cent lower in frequency, or at 3.5 MHz.

Thus the system was complete — using three radiators, three radial reflectors, and three parallel reflectors. With the aid of a large number of comparative signal-strength readings — taken in the receive mode (using a Drake R-4A receiver) to eliminate the S-meter variable — a beam pattern was developed, as shown in fig. 4. Also shown in fig. 4 is the ideal pattern for a two-element vertical array using quarter wavelength spacing. It can be seen that the sloper pattern compares quite favorably in horizontal directivity. Remember that this data indicates only in the horizontal plane, not vertical, and that it indicates directivity, not gain — gain being a function of directivity and efficiency.

The system has been used for several years and has provided excellent, consistent, and reliable performance. It's been a great asset in digging DX out of the QRM and has always given an excellent account of itself in the pileups.

*Not a very good test from an engineering standpoint, but one used by hams for years. Use caution and make certain you are insulated from ground.

Every YF-370 is factory assembled, tested, and includes diode protected meter movement with a fused input and an extra fuse. The switch assembly has double wiping gold plated contacts to assure years of trouble-free service. At this low price buy two...one for the car and one for the shop.
antenna-performance measurements using celestial sources

High-performance vhf and uhf arrays for moon-bounce, meteor, and tropo scatter are proliferating in the Amateur Radio ranks. This article describes a simple procedure for measuring the receiving figure of merit of large vhf and uhf arrays using radio stars, the moon, or the sun as a source. I developed the technique from the references and recently used it to measure the performance of the 25.6-meter (84-foot) moonbounce dish at K3NSS.

The method derives the ratio of the antenna gain, \( G \), to the receiving system noise temperature, \( T \), or \( G/T \). \( G/T \) is a measure of system receiving sensitivity and applies directly in link calculations and serves as a standard for performance comparison. Knowing \( G/T \) and either the antenna gain \( G \) or the system noise temperature \( T \), the unknown parameter can be derived.

**measurement procedure**

\( G/T \) is measured from celestial sources by taking the ratio of the received signal* noise power to the noise power received from the cold sky. This ratio, called the \( Y \) factor, is compared with the known radiation flux density, \( S \), of the source (table 1) to determine the receiving system figure of merit, \( G/T \) (eq. 1). Units of \( G/T \) are decibels per degree Kelvin, dB/°K.

The advantages of this technique are simplicity

*The signal of these celestial sources has noise characteristics.

By William H. Curry, Jr., W5CQ/W4RXY, 11003 Blue Roan Road, Oakton, Virginia 22124
Frequency — GHz

Fig. 1. Solar flux density vs. frequency for July through December, 1978.

and accuracy. The technique is elegant because it requires no knowledge of either antenna gain, $G$, or system noise temperature, $T$. The critical measurement, $Y$, is calculated as a ratio so that measurement units and biases cancel. Finally, no special equipment beyond that for normal station operation is necessary. Only a suitable measure of receiver output power is required. This could be from the receiver $S$-meter, although better accuracy will result if a simple diode noise detector is used, as described in reference 1.

The qualifying minimum performance necessary to use this procedure is that the system must be able to detect sun noise, which is the strongest source. Measurement accuracy depends on the following factors:

1. **Source used.** The flux density, $S$, of the sun varies randomly by a factor of two or more. Therefore measurements from the sun may not be accurate within 3 dB unless corrected for actual solar flux at the time of observation (see table 1 and fig. 1). If $G/T$ is large enough to permit radio star measurements, accuracies to within 0.5 dB are attainable under favorable reception conditions.

2. **Atmospheric/ionspheric attenuation.** Source attenuation varies inversely with frequency and elevation angle. Observations at 144 MHz near the horizon may not be accurate within 3 dB. Observations of Cassiopeia A or Cygnus A at 1296 MHz, at elevation angles greater than 45 degrees, can be accurate to ±0.5 dB. The references contain additional information for those interested in corrections to obtain the greatest possible accuracy.

3. **Number of measurements.** Averaging a large number of observations, or applying linear regression analysis, will result in improved accuracy.

4. **System noise floor.** The more sensitive the system, the more attention must be paid to cold sky noise. It illustrates the relatively high noise characteristic of the galactic equator and the relatively low sky noise at the galactic poles. The more sensitive the system, the more attention must be paid to cold sky noise.
The K3NSS 25.6-meter (84-foot) parabolic reflector in the stow position. A small group from the Southern Maryland Amateur Radio Club, including the author, restored the antenna to 432-MHz moonbounce. All rf systems, including the feedlines and feed antenna, were missing. The 432-MHz system was built and installed from individual and club assets. The restoration began in the fall of 1976, and the first contact was completed with LX1DB in April, 1977.

temperature. For example, to take readings from the moon, which has a very weak $S$, care would have to be taken to ensure that the cold sky reading was from a low noise area. This isn’t as important for sun measurements. The objective is to get large $Y$ factor measurements.

**measurements**

The algebraic relationship of $G/T$ to the $Y$ factor and source intensity, $I(s)$, is given by:

$$ G/T = \frac{Y}{I(s)} $$  \hspace{1cm} (1)

where:

- $Y = \text{signal noise power (source)} / \text{cold sky noise power}$

- $I(s) = \frac{\lambda^2 S}{8\pi K}$

$\lambda$ = wavelength (meters)

$S$ = source flux density from table 1 (watts per square meter per Hertz)

$K$ = Boltzmann’s constant

$= 1.38 \times 10^{-23}$ joules per degree Kelvin

Eq. 2 translates the source flux density, $S$, to units of equivalent temperature, $T$. It includes a factor $(1/2)$ to account for the unavoidable loss resulting from the interception of a randomly polarized signal by an antenna sensitive to a single polarization. The factor $\lambda^2/4\pi$ accounts for the antenna gain relationship to wavelength (area factor).

The $Y$ factor used here differs from that described by K2LMG and W2YBP in reference 1, but the principle is the same. WABIQN, reference 3, describes a sun-noise measurement procedure using an estimate of antenna gain by use of horizontal and vertical measurements.

A view showing the antenna feed supporting the radiating element (dipole) covered by a polyethylene bag at the focus. The Gregorian reflector, supported by the 5.5-meter (18-foot) fiberglass tripod, was not usable in the restoration. Instead, the dipole feed was mounted on a feed tower, clamped at the base to a rotator for polarization control. The coaxial feed tower was made from 7.6-cm (3-inch) diameter aluminum irrigation pipe with a 3.5-cm (1-3/8-inch) diameter copper water pipe as a center conductor. The focal length of the dish is 7.6 meters (25 feet).
beamwidths, $\theta h$ and $\theta v$. The procedure described here will yield better accuracy.

Eq. 1 is an algebraic ratio. The $G/T$ value is more useful in logarithmic (decibel) units. Therefore the following conversion applies to the $G/T$ ratio from eq. 1:

$$G/T (dB/\circ K) = 10 \log_{10}[G/T \text{ ratio from eq. 1}]$$ (3)

Remember that algebraic ratios usually result from, or are used in, equations with multiplication and/or division terms. Equations employing or yielding logarithmic values usually have addition and/or subtraction terms. Eq. 1 written for logarithms is:

$$G/T (dB/\circ K) = 10 \log_{10}(Y - 1) - 10 \log_{10}[T(s)]$$ (4)

Typical $G/T$ values for Amateur arrays range between $-10$ and $+15 \text{ dB/\circ K}$.

Those interested in the derivation and further explanation concerning radio astronomical measurements of antenna performance should consult references 4 through 8. Wait (reference 4) presents a clear derivation of eq. 1, and the remaining references contain extensive information dealing with every aspect of radio astronomy measurements.

measurement techniques

The ease and accuracy of measurements depend greatly on your ingenuity. The following observations are submitted as food for thought:

1. Receiver linearity. The receiver chain must be operated linearly over the dynamic range of the measurements. As a starter, the receiver agc must be defeated.

2. Receiver bandwidth. The i-f should be operated at the widest possible bandwidth, since noise-power measurements are involved.

3. Measuring the $Y$ factor. An accurate measurement technique is to note the cold sky power, then acquire the source; then, by use of a precision variable attenuator, reduce the source signal to equal the previous cold-sky reading. The required attenuation is the $Y$ factor. Caution: remember to convert decibel readings to algebraic ratios and vice versa as applicable.

Notes: 1. The value for sun $S$ varies randomly by a factor of two or more. The value listed is typical for a quiet sun.
2. Calculated by the author from the relationship: $S = (2K T m/\pi^2) \Delta m$ where $\Delta m =$ solid angle subtended by the moon viewed from earth. See reference 7.
3. $S$ decreases approximately 1 per cent per year. Value corrected by the author to 1978. See references 5 and 6.
4. 144 MHz values extrapolated by the author. Expect large measurement variations because of atmospheric and ionospheric effects.
5. Daily solar radiation measurements are available from the Space Environmental Laboratory, 325 Broadway, Boulder, Colorado 80302. Data is available to remote computer terminals by contacting J. D. Schroeder at (303) 499-1000, extension 3780.
4. Power vs voltage measurements. Be sure to measure the Y factor as a power ratio. Most meters and chart recorders respond to voltage or current, not to power. Squaring a voltage or current ratio yields the corresponding power ratio.

5. Acquiring the source. Locating a source in the sky is a matter of determining its Greenwich hour angle, GHA, and declination for the time of observation. Table 2 lists celestial coordinates (right ascension and declination) for stellar sources. Reference (9) gives GHA and declination directly by hour for the meter (84-foot) parabolic reflector at Cheltenham, Maryland, to moonbounce operation, including the measure of performance from Cassiopeia A. That effort was the inspiration for this article.

### Table 2. Location, advantages, and disadvantages of celestial sources for antenna-performance measurements.

Note 1. Right ascension and declination are coordinates on the celestial sphere. See references 9 and 10 to convert to antenna pointing coordinates for local time.

measurement refinements

There's much more to be said regarding measurements of high-performance antenna systems using celestial sources. For example, the determination of antenna gain, G, by measuring the equivalent system noise temperature, T, is not yet adequately addressed in Amateur Radio literature. Several rather esoteric correction factors not covered in this article are available. These include corrections for propagation attenuation and source polarization asymmetry (stellar sources). Those who strive for absolute precision may be interested in the more detailed discussions on factors affecting measurement accuracy contained in references 4 through 6.

acknowledgments

I'd like to thank Ruth Phillips, K3AGR; Howard Eich, W3HE; Jim Erickson, K3LFO; Dave Phillips, W3JPM; and Willie Mank, W1ZX; all made major contributions to the restoration of the K3NSS 25.6-meter (84-foot) parabolic reflector at Cheltenham, Maryland, to moonbounce operation, including the measure of performance from Cassiopeia A. That effort was the inspiration for this article.

STEP UP TO TELREX
Professionally Engineered Antenna Systems

Single transmission line "TRI-BAND® ARRAY"

"MONARCH" 10, 15, 20 Meter
Model TBSEM/4KWP

"MONARCH" 10, 15, 20 Meter
Model TBSEM/4KWP

ONLY TELREX GIVES YOU ALL THESE FEATURES...
- Power rating 4 KWP... rain or shine.
- Wind rating survival 110 mph
- Patented broad-band coaxial "Balun"
- Heavy-duty steel gusset mounting plate.
- Aluminum boom 2", 2-1/2" O.D. x 18 ft.
- Large diameter, .058 wall taperswaged dual elements for minimum weight and exceptional strength to weight ratio.
- Stainless steel electrical hardware.

By the only test that means anything... on the air comparison... this array continues to outperform all competition... and has for two decades. Here's why... Telfex uses a unique trap design employing 28 HQ7500 V ceramic condensers per antenna. Telrex uses 3 optimum-spaced, optimum-tuned reflectors to provide maximum gain and true F/B Tri-Band performance.

At 50 ft. or more (above ground) a rugged Telrex "Tri-Band" is the only answer to longevity... a true money saver.

For technical data and prices on complete Telrex line, write for Catalog PL-7.

More than 15,000 Hams are on the air with the ATLAS 210x!

It's a Proven Winner!

- HF SSB/CW Transceiver
- No transmitter tuning
- Plug-in circuit boards
- Super selectivity with exclusive 8 pole crystal ladder filter
- Exceptional immunity to strong signal overload and cross modulation
- Slips in and out of special mobile mounting bracket or AC console in seconds

For complete details see your Atlas dealer, or drop us a card and we'll mail you a brochure with dealer list.

200 Watts • 5 Bands • All Solid State
3½” x 9½” x 9½” • 7 Pounds

Don't let its fingertip size fool you. The Atlas 210x transceiver has all the power and performance that you find in rigs twice as big and costing twice as much.

And with over 15,000 Atlases on the air, you know you're getting a proven winner.

Model 210x or 215x Transceiver .......................... $765
(With noise blanker installed add $45)
Plug-in Mobile Kit ........................................... $ 55
Portable AC Supply 110/220V .............................. $105
AC Console 110/220V ......................................... $155

self-gating the 82S90/74S196 decade counter

In many typical counter circuits, the clock input to the first decade counter is logically combined with the count gate prior to being applied to the counter. In some cases, the limiting frequency factor is then the external gate and not the first decade counter. Fig. 1 shows a method of using the internal circuitry of the In addition, the counters also ignore any inputs on the clock lines. By tying the load lines to the output lines, the information is held, while it is processed through to the readouts. A negative reset pulse will reset all flip-flops to zero, ready for the next count period.

fig. 1. Schematic diagram of a method for using the internal gating in the 82S90/74S196 counter to eliminate any external clock gates. By using the count gate to control the Count/Load line, the IC will ignore any pulses on the clock line when the counters are used as latches.

82S90/74S196 to perform the gating, thus allowing the IC to be used to its full 100-MHz capability without any degradation caused by external gating.

When the Count/Load line and the Rest line, pins 1 and 13 respectively, are high, the counter will operate in a normal clocked fashion. Since the count gate is connected to the Count/Load line, the counter will continue to function for the length of the gate. However, at the end of the counting time, the count gate goes low, shifting the IC into a mode where the counters actually act as latches fed from the Data Input lines.

metalized capacitors

Where the need exists for a very small size, low cost, stable, close tolerance capacitor in the range of 0.001 to 2.2 μF with good high-frequency characteristics, the Siemens MKM and MKH types are a good choice. They can be obtained in either metalized polycarbonate or metalized polyester, with 5 per cent tolerance, rated at 100, 250, or 400 volts. As an example of their compactness, the 0.47 μF, 100 volt capacitor measures a 1 x 1 x 0.5 cm. The feature that attracted me most was their very low parasitic inductance of 20 nH; this is due to the stacked foil construction and the package design which allows very short lead lengths. Several values were checked for series resonance with 3 mm leads; values for two popular ceramic values are included in the list below for comparison:

<table>
<thead>
<tr>
<th>Capacitor</th>
<th>Value</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ceramic</td>
<td>0.02 μF</td>
<td>12.0 MHz</td>

</tbody>
</table>

Stability of the Siemens capacitors, of course, is not as good as polystyrene or silver mica, but I find them very useful for timing circuits, active filters, and similar applications.

Bill Wildenhein, W8YFB
cure for the R4C backlash

Shortly after I received my new R4C, the dial started to develop a backlash problem. At first glance, it appeared that the clearance between the nylon gears was not correct. However, upon closer examination I determined that the backlash was caused by a binding of the outer edge of the plastic concentric dial closest to the front panel. In order to get a better look at the problem, I removed the white metal bracket that has the pilot lamp socket attached to it. This bracket is attached to the front panel by a machine screw on each end.

Each machine screw has a metal spacer between the bracket and panel. While removing the screw, hold the spacer with a long-nose plier or it will fall down into the bottom of the chassis necessitating the removal of the bottom cover in order to retrieve it.

After removal of the bracket, you will notice two felt pads on each end of the plastic index plate attached to the front panel. Remove these two pads completely. These pads were
added by Drake to prevent the concentric dial from rubbing on the plastic index plate, which could warp with age.

Drake has since corrected the problem on their later production runs by relocating the index plate from the inside of the panel to the front of the panel. The felt pads have also been removed.

Bernard White, W3CVS

autek filter

The Autek OF1 ssb/CW active filter has proven itself to be a very useful device. Like any other “black box” in the typical ham shack, on-the-air use indicates certain modifications would make it far more useful.

Since the QF1 operates from the ac line, a low-drain indicator light would show when the power is on. This is easily accomplished with an LED mounted just above the NOTCH control on the front panel. A 15-Vdc supply is available, with the appropriate series resistor, you have a light, color of your choice.

The second modification allows the operator to switch the filter in or out of the circuit. Thus, the headset/speaker can monitor either the filter or the direct output from the receiver. This is very easily accomplished with a miniature double-pole, double-throw switch installed just to the left of the existing ac switch. An equalizing control was included to prevent overloading the Autek Amplifier. Thus, the phones will hear basically the same level in or out of the filter. Since the pot requires very little adjustment, it was mounted on the rear, just below the three-lug strip. This three-lug strip is the tie point for the filter input, making modification very simple.

Bill Long, K6EVQ.
Bob Landgrave, WA6WZQ

improved stability for the 32s transmitter

While operating CW “split” with my Collins 32s-1/75s-3 combination, I noticed a definite frequency shift on the transmitter signal. This occurred only on the first dash or couple of dots when using VOX CW keying, being most noticeable on 10 meters. When PTT was used, the drift was completely unnoticeable.

My transmitter is a modified 32s-1 which has been up-dated to an S-3.1 A zener diode provides regulation for the B-plus supply to the HFO and PTO. The stock 32s-3 also regulates the voltage to these oscillators, but it is supplied by an OA2. Examination of the circuit revealed that the voltage for the regulators is derived from the +275 volt input via a set of contacts on the VOX relay, K1 (see fig. 3). This means that during receive mode, there is no voltage applied to the HFO or PTO, with the transition from zero to full operating voltage (regulated or not) causing the oscillators to shift frequency slightly.

By changing the circuit to maintain voltage on the regulators, and hence the oscillators during receive, this anomaly is avoided. Simply move the lead connecting R17 to the VOX and connect it to C137 on the power amplifier cage wall. This capacitor has +275 volts applied continuously.

After this change is made, VOX keying will be just as good as with PTT, with no shift discernible. However, the effectiveness of this modification to an unmodified 32s-1 has not been determined.

reference

Paul Pagel, N1FB

fig. 2. Diagram of the modifications to the QF1 audio filter. The power-indicating LED is mounted in a 5-mm hole just above the NOTCH. To allow the operator to switch the QF1 in and out of the circuit, a miniature double-pole, double-throw switch was installed in the indicated position.

fig. 3. By changing the connection to R17, the oscillators are energized at all times. This eliminates the frequency shift caused by switching their plate voltage.
The Personal Antenna
...Custom created with Hustler components.

Make your choice of Hustler components. Aluminum and chrome plated brass mast with bumper mounting or stainless steel 180° adjustable ball fender/deck mount. Standard 500 watt PEP resonators or Super 2 KW PEP resonators with large 'Hi-Q' computer designed inductor and stainless steel tip rod. Optional quick disconnect stainless steel resonator spring. Quality manufactured 50 ohm coax. You want top performance. That's why you should customize with the MO/RM series antennas and components from Hustler, the name recognized for personal quality in antennas!

- Extremely rugged

LUNAR'S NEW MODEL
2M 10-150 LINEARIZED AMP
Now ready and being shipped. We held off on announcing it until it was right...
Ready now. Order today from your Lunar dealer.

LUNAR'S TRANSVERTER SYSTEMS
Individual modules and other accessories are available for up and down converter systems. Can be connected in any combination your system dictates. Write for complete list of modules and accessories.

Heavy Duty Power Supplies from ASTRON
High Quality • Rugged • Reliable

SPECIAL FEATURES
- SOLID STATE ELECTRONICALLY REGULATED
- FOLD-BACK CURRENT LIMITING Protects Power Supply from excessive current & continuous shorted output
- CROWBAR OVERVOLTAGE PROTECTION on Models RS-7A, RS-12A, RS-20A, & RS-35A
- MAINTAIN REGULATION & LOW RIPPLE at low line input Voltage
- HEAVY DUTY HEAT SINK • CHASSIS MOUNT FUSE
- THREE CONDUCTOR POWER CORD
- ONE YEAR WARRANTY • MADE IN U.S.A.

PERFORMANCE SPECIFICATIONS
- INPUT VOLTAGE: 105 - 125 VAC
- OUTPUT VOLTAGE: 13.8 VDC ± 0.05 volts (Internally Adjustable 11-15 VDC)
- RIPPLE: Less than 0.5% peak to peak (full load & low line)
- REGULATION: ± 0.05 volts no load to full load & low line to high line

Other popular POWER SUPPLIES also available: (Same features and specifications as above)

DSI
QUIK-KIT®

50 HZ TO 550 MHZ COUNTER KIT
95% ASSEMBLED 100% TESTED
Performance You Can Count On

FREQUENCY COUNTER APPLICATION:
- Ham Radio — Two Way Radio — CB
- Audio Amplifier & Receiver Repair
- Computer Maintenance & Construction
- A Must for TV & PLL Repair

$99.95
MODEL 3550K
includes built-in
Pre-Amp & Prescaler

DSI OFFERS THE BEST OF TWO WORLDS...
An unprecedented DSI VALUE... in a high quality, LSI Design, 50 HZ to 550 MHZ frequency counter kit. And, because it's a DSI innovation, you know it obsoletes all competitive makes, both in price & performance.

With 95% of the assembly completed by DSI, you are only one hour away from solving all of those difficult bench problems, rom adjusting 60 HZ clock-time bases to setting the frequency of a 468 MHZ Mobile Radio.

FACT: Every 3550 QUIK-KIT® PC board is factory assembled and tested before shipment. FACT: The problems of bad LED's, C's, and Capacitors are a thing of the past. FACT: No manufacturer except DSI offers a 550MHZ frequency counter with...

DSI — GUARANTEED SPECIFICATIONS
Time Base TCXO 1PPM 65° to 85°F
Freq. Range 50HZ to 550MHZ incl. two SO239 inputs
Resolution 1HZ to 55MHZ, 10HZ to 550MHZ
Gate Time 1 sec & 1/10 sec with Auto Decimal Point
Display 8 digits, ½ inch LED with Leading Zero Blanking
Sensitivity 25MV @ 25MHZ, 150MHZ, 550MHZ;
75MV @ 450MHZ
Power Batt., 12VDC @ 300Ma, 110VAC (with AC-9)

DSI INSTRUMENTS, INC.
7924 Bonson Road Dept. G, San Diego, CA 92111
loop antenna

A new receiving antenna for the 80- and 160-meter Amateur bands, the broadcast, and the VLF bands has been introduced by Palomar Engineers.

The loop rotates 360 degrees in azimuth and ±90 degrees in elevation with calibrated scales for both. The elevation or "tilt" of the loop is a new feature of the Palomar Engineers design and gives much deeper nulls than ordinary direction finder loops.

Loop nulls are very sharp on local and ground wave signals, but are broad or nonexistent on distant skywave signals. This allows local interference to be eliminated while DX stations can still be heard from all directions.

The loop picks up much less noise than the usual transmitting antenna. This, along with its ability to null out specific interfering signals, improves reception considerably.

A Loop Amplifier serves as the mounting base for the antenna. It contains a tuning capacitor to resonate the loop and an amplifier to boost the signal and preserve the high Q of the loop. The Loop Antenna plugs into the amplifier.

Plug-in loops are available for 160/80 meters (1600-5000 kHz), broadcast band (550-1600 kHz), and VLF (150-550 kHz).

A free descriptive brochure is available from Palomar Engineers, Post Office Box 455, Escondido, California 92025.

Cushcraft mobile antennas

Cushcraft has introduced two new high-performance vhf/uhf mobile antennas. They feature 3-dB gain with 5/8-wavelength stainless steel whips and precise frequency adjustment by means of a finger-tip collet. There are trunk lip and magnetic mount models which have been tested to speeds in excess of 90 mph. The antenna packages include 5 meters (18 feet) of RG-58/U cable with connectors, plus car-finish protective pads.

The vhf models cover 144-174 MHz, including the 2-meter fm sub-band. The uhf model covers 220-225 MHz.

For more information write to Cushcraft Corporation, P.O. Box 4680, Manchester, New Hampshire 03108.

220-MHz fixed-station antenna

The all-new Hustler 220-MHz vertical fixed-station Amateur antenna, designated the Model G7-220, was recently introduced by New-Tronics Corporation of Brookpark, Ohio. The G7-220 marks New-Tronics' entry into the now-popular 220-MHz band and complements their existing base and mobile Amateur antenna line. The superior 7-dB gain of the antenna, for both transmitting and receiving, makes it the most powerful omnidirectional 1 ½-meter antenna available. The all-new rugged design of the Hustler G7-220 antenna keeps the signal radiation pattern at the lowest possible angle to the horizon for maximum efficiency and longest range.

The Model G7-220 has an SWR of 1.5:1 across its entire 5-MHz bandwidth, with SWR at resonance at 1.2:1 at the antenna. The radiating elements of the Hustler G7-220 are dc grounded for lightning protection and the antenna has a 50-ohm base impedance.

This new Hustler 220-MHz vertical combines the latest antenna technology and the best available corrosion-resistant materials for extra-long life. Only Hustler uses all stainless steel hardware in Amateur and professional products. Each component is precisely built for quick and easy assembly.

The all-new Hustler G7-220 (1 ½-meter) Amateur vertical fixed-station antenna has a suggested list price of $119.95 and is available now. For fur-
Aluma Tower Company of Vero Beach, Florida, announces a new series of towers. Named "Mobile Van Towers," these towers are perfect for signal communications work, all types of test work (radio signals, air sampling), Civil Defense mobile communications, and Amateur Radio.

The tower is mounted on a standard ladder rack on top of a van. It is transported in a horizontal position, and, when at the selected site, is easily tilted to the vertical position and cranked up to the desired height. The feature that makes this tower different from the standard Aluma Tower is the unique sliding track design, which enables the operator to put the tower from the horizontal to the vertical position and back to horizontal with a minimum of effort.

The tower is made in three standard-duty models - 35, 50, and 60

feet — and two heavy-duty models for internally mounted rotors — 35 and 50 feet.

Aluma Tower Company plans to market this tower across the country through their network of dealers, concentrating on TV installation experts and Civil Defense units.

For more information, please contact Aluma Tower Company, 1639 Old Dixie Highway, Vero Beach, Florida 32960.

Antler 2-Meter antenna

A new quarter-wave, magnetic, roof or cowl-mount antenna has been announced by Antler Antennas. The new model covers 144 to 148 MHz and features a powerful, permanent base that firmly grips any flat, steel surface.

The magnet base is fitted with a wide, low-profile, chrome-plated base which allows the factory-wired coax to exit and lie flat against the vehicle’s roof to reduce the wind whip and noise often encountered with this type of antenna system. Requiring no installation, the antenna is easily removed for storage to prevent theft.

The unit is designed for in-city hams for whom overhanging obstructions, low garages, and parking facilities present problems.

The new antenna joins a complete...
line of quarter-wave and 5/8-wave 2-meter models produced by Antler Antennas and sold through distributors and dealers nationwide. For more information, write Antler Antennas, 6200 South Freeway, Fort Worth, Texas 76134.

invisible 10-meter mobile antenna

The "Ten/Tenna," for 10-meter and CB use, mounts inside metal-roofed vehicles and excites the car shell into radiation as a 10-meter or CB antenna. The complete kit includes matching network, coaxial cable, and all required mounting hardware. The matching network includes a tuning indicator which dims at low swr. The kit is priced at $27.40 postpaid. A complete report is available free, from Dept. HRR1, Microwave Filter Co., Inc., 6743 Kinne St., East Syracuse, New York 13057.

rf micro-volt meter

RMS Electronics recently introduced its new Model 10-500 RF $\mu$V Meter. This meter is ideal for bench or field use and offers, for the first time, a compact battery-operated meter with sensitivity of 10 $\mu$V over a bandwidth of 10 to 500 MHz and is usable from 1 through 800 MHz. The Model 10-500 RF $\mu$V Meter is perfectly suited for testing two-way radio receivers, antenna systems, CATV distribution amplifiers, and the like. The unique design of the instrument is such that it may be upgraded for wider bandwidth to 1000 MHz by the user if future needs demand this. For additional information, contact RMS Electronics, Inc., 2412 Crystal Drive, Ann Arbor, Michigan 48104.

FAIR RADIO SALES
101A EUREKA - Box 1105 - LIMA, OHIO - 45802
fact:
our quality assurance is your performance insurance.

Originally designed for battlefield ruggedness, the microphone elements in Shure mobile and communications microphones offer unequalled reliability. Our quality control engineers anticipate the worst possible field conditions. These microphones have been subjected to the most rigorous tests in the industry, including six-foot drops onto hard floors; violent vibration tests; temperature variation tests ranging from a bitter -54°F. to a searing 185°F.; and 100% humidity tests. We've even dragged them behind automobiles on open roads and subjected them to a battery of corrosion tests. And yes, they really work after all that!

**Exclusive Three-Way Flex Tester**

Shure knows that the single most common cause of microphone malfunction is failure of the cord. An exclusive Shure-designed story-and-a-half tall microphone cord tester dishes out more abuse than the average microphone gets in a lifetime.

Stretch, rock, and twist; first, the cord tester stretches the microphone to the full length of the cord. Then it simultaneously rocks the microphone 270° at the end of the cord while it gives the microphone a violent 90° twist in two directions. And this goes on day after day!

**3-D Shake Tester**

A microphone that fails spells disaster for a mobile communications system. Every Shure microphone is designed to withstand hours in our brutal 3D Shake Tester — simulating years of driving over rough, bumpy roads.

**Million-Cycle Switch Tester**

Another abused microphone component is the switch. Shure-designed long-life leaf switches operate with a wiping action that resists the buildup of corrosion and dirt. And Shure's ongoing tests show that they continue to make contact reliably and positively after one million switching operations.

The name Shure Brothers Inc. on the back of your mobile microphone is your assurance of proven quality and reliability.

Shure Brothers Inc., 222 Hartrey Ave., Evanston, IL 60204. In Canada: A. C. Simmonds & Sons Limited

Manufacturers of high fidelity components, microphones, sound systems and related circuitry.
Repeater Jammers Running You Ragged?

Here's a portable direction finder that REALLY works—on AM, FM, pulsed signals and random noise! Unique left-right DF allows you to take accurate (up to 2°) fast bearings. Its 3dB antenna gain and .06uV sensitivity allow this crystal-controlled unit to hear and positively track a weak signal at very long ranges—while the built-in RF gain control with 120 dB range permits positive DF to within a few feet of the transmitter. It has no 180° ambiguity and the antenna can be rotated for horizontal polarization.

The DF is battery-powered, can be used with accessory antennas, and is 12/24V for use in vehicles or aircraft. It is available in the 140-150 MHz VHF band and/or 220-230 MHz UHF band. This DF has been successful in locating malicious interference sources, as well as hidden transmitters in “T-hunts”, ELTs, and noise sources in RFI situations.

Price for the single band unit is $195, for the VHF/UHF dual band unit is $235, plus crystals. Write or call for information and free brochure.

PRE-SELECTOR FILTERS

ATV FILTERS

ELIMINATE IMD "BIRDIES" (CAUSED BY OUT-OF-BAND TRANSMISSIONS) AND IMAGE FREQUENCY NOISE FROM YOUR RECEIVER SYSTEMS.

BAND FILTERS:

PSF144 $89.95
PSF432 $53.95
PSF1296 $53.95
PSF1691 $55.95

ATV Channel Filters:

PSF426-ATV $89.95
PSF438-ATV $89.95

Shipping $3.50

OSCAR–J FILTERS

Suppress 2m Tx Third Harmonics. Low 2m loss (0.5dB typ.). High loss at 435 MHz (30/40dB).

MM200-5

30 dB min. atten. $29.95

MM200-7

40 dB min. atten. $39.95

Shipping $2.50

TRANSVERTERS

Use your HF transceiver on the VHF/UHF bands with the addition of a transverter. Both the transmit up-converter and the receive down-converter are built into one package. Typically IFs available are 10M also 5M and 2M. Internal T/R switching eliminates need for external relays. Some models have VOX circuit. Typical output power 10 watts minimum. Typical receive NF 3.0 dB, 12 volt operation. Models available for CW, AM, FM, SSB, RTTY, OSCAR, ATV operation. Ask for detailed specifications.

Prices from $175.00 Shipping $3.50

ANTENNAS

UHF LOOP YAGIS

26 LOOPS GAIN +20 dBd
1250-1340 MHz 1296-LY $56.95
1650-1750 MHz 1691-LY $59.95

420-450 MHz MULTIBEAMS

for OSCAR, TROPO and ATV Communications

48 EL. GAIN +15.7 dBd 70/MBM48 $54.95
88 EL. GAIN +18.5 dBd 70/MBM88 $79.95

RECEIVE CONVERTERS

ATV CONVERTERS

Converters for all bands 50 MHz through 1691 MHz (2304 MHz coming soon). Twin crystal models at 432/435 for OSCAR work. Wideband ATV models and Low NF options at 70cm.

10M, 6M, 2M

Prices from $359.95 Shipping $2.50

LINEAR AMPLIFIERS

EDL432 (illus.) $154.95
EDL432P, inc's power supply & cabinet $329.95
Both models 50W out for 10 W drive.

2M Models

2M10-80P $199.95
2M10-150P $289.95
2M25-150P $269.95

Shipping, via UPS at cost.

**RTTY for ALL Systems**

**ELECTROCOM® “SERIES 400” FREQUENCY SHIFT CONVERTERS**

Professionally engineered for outstanding performance, stability, and reliability, the Electrocom Models 400 and 402 add new dimensions of compatibility between radio and teletypewriter systems. Manufactured to highest quality standards—an Electrocom tradition for nearly two decades—these units are ideal for military, government, commercial, civil defense and amateur applications. The Model 400 front panel digital knob accurately selects shifts up to 1000 Hz., while two such knobs on the Model 402 independently set the mark and space frequencies. Both models may also be preset with any tone pair between 1000 and 3200 Hz.

Optimum performance with FSK or AFSK systems is assured by matched filters, precision linear detectors, baud rate selector, bias compensation, and semi-diversity circuitry. Operation is enhanced by a CRT monitor, autostart with solid-state motor switching, antispaces, markhold, EIA/MIL output voltages, and a constant current loop supply. In addition, various options are available including rack mounting and polar current output.

Write or call us for complete product details and specifications. Learn why Electrocom “400” Converters are designed not only for today’s communication environment, but ultimately to fulfill RTTY requirements for years to come.

VIDEO TERMINAL

A completely self-contained, stand alone video terminal kit. Requires no hubboard and TV set to become a complete terminal unit. Two units available, common features are: single 5V supply, XTL controlled sync and baud rates (56KHz), complete computer and keyboard control of cursor. Parity error control and display Accepts and generates ASCII plus parallel keyboard input. The 3216 is 32 character, 16 lines, 2 pages with membrane feature. The 6416 is 64 character, 16 lines, with scrolling, upper and lower case (optional) and has RS-232 and 20mA loop interfaces on board. Kits include sockets and complete documentation.

- RE 3216, terminal card
  $149.95
- RE 6416, terminal card
  $189.95
- Lowest Case option, 6416 only
  $139.95
- Power Supply Kit
  $14.95
- Video/RF Modulator, VD-1
  $6.95
- Assembled, tested units, add
  $60.00

CALENDAR ALARM CLOCK

The clock that's got it all. 6" LCDs. 12-24 hour, snooze, 24 hour alarm, year calendar, battery backup and lots more. The super 7001 clock is used Size 3x4x2 inches Complete kit less (case option)

DC-9
$34.95

30 Watt 2 mtr PWR APM

Simple Class G power amplifier features 8 times power gain 1 W in for 25 W out for 300 hours. Max. output of 35 W, incredible value, complete with all parts, case less and TR relay

PA-1, 24 W power amp kit
$22.95
TR-1, RF sensor TR relay kit
$6.95

FREQUENCY COUNTER KIT

Outstanding Performance

Incredible Price

The CT-50 is a versatile and precision frequency counter which will measure frequencies to 60 MHz and up to 600 MHz with the CT-600 option. Large scale integration, CMOS circuitry and solid state display technology have enabled the circuitry to match performance found in units selling for over three times as much. Low power consumption (typically 300-400 ma) makes the CT-50 ideal for portable battery operation. Features of the CT-50 include: large scale digital display, RF input, switched CMOS technology, fast response, automatic decimal point, fully socketed IC chips and input protection to 50 volts to insure against accidental overload or load. And the best feature of all is the easy assembly. Clear step by step instructions guide you to a finished unit you can rely on.

BISHOP HILL — BISKOPSULLA RADIO EXCHANGE AMATEUR RADIO OPERATORS in Sweden and the United States will attempt direct radio contact between Bishop Hill, Illinois, and Biskopskulla, Uppland, Sweden on the weekend of May 26 and 27, 1979. Bishop Hill was a Swedish settlement established in the 1850's by Swedish migrants and is now an historical site maintained by the State of Illinois. Led by DXers W5FK2 and SMI2FY, the groups will try to contact as many stations as possible over the scheduled weekend. Operation will occur on all bands, phone and CW, full period. Special QSL's will be issued, SASE or IRC's requested, all others via bureau. The Biskopskulla team will use the call SMQ3M, the Bishop Hill group will use W5FFK2. QSL via W5AGN.

MASSACHUSETTS: The NSBARC Hamfest July 21, 22 at Cummington Fairgrounds. Tech talks, demonstrations and dealers. Flea market, $1.00, advance registration $2.00 single, with spouse $5.00 to Tom Hamilton, W1VFX, 206 California Avenue, Pittsfield, Massachusetts 01201 or $4.00/6.00 at gate. Mobile talk-on: 148.3191. Gates open at 5:00 PM on Friday for free camping.

SOWP 4TH ANNUAL CW QSO PARTY Sponsored by the Society of Wireless Pioneers (SOWP), From 0000 Z on June 6 through 2359 Z on June 7. There are no formal requirements except to exchange an atom of name, membership number and QTH. Suggested frequencies are 55 kHz (±5 kHz) up from the low end of each amateur band. Novices will operate in the center of each novice band. Competitors who can only participate part-time are requested to make their calls on the even hours during the period. To optimize long distance contacts, it is suggested that ten and fifteen meters be used from 1400 to 2100 hours Z. The call will be CU SOWP. A special certificate will be available to all members who contact a minimum of ten other members during the event. Requests for the certificate must include a list of stations contacted, dates, times and membership numbers. In addition, an SASE must be included. Certificates will be issued by the V.E. for Awards, Manuel "Pete" Fernandez, WMM7, 129 Haley Road, Greenville, South Carolina, 29607. Requests must be submitted not later than 30 June 1979.

NEW ENGLAND: The Hostaders Net will hold its Sixth Annual Tailgate Swapfest, Saturday, May 12, at the Deerfield, New Hampshire, Fairgrounds (covered buildings in case of rain). Admission: one dollar, no permission or commission, commercial dealers welcome at same rate. No admission benefit Boston Bruins Unit of Shriners' Hospital for Crippled Children. We were $1140.50. Talk on 52 and 146.417.00. Questions about New England's biggest flea market? SASE to Joe DeMasi K1RGG, Star Route Box 56, Bucksport, ME 04616, or Norm Blake, WA1VVB, P.O. Box 32, Cornish, ME 04020.

PENNSYLVANIA: Fifth Annual Northwest PA Hamfest, Saturday, June 9, 1979, Crawford County Fairgrounds, Meadville, PA. Note date change. Gates open at 8:00 AM. Bring your own tables. $2.00 in; $1.00 out to display. $2.00 admission. Hourly door prizes, raffles, refreshments, commercial displays welcome. Talk on 044/6, 812/1, 6303. Details C.A.R.S., P.O. Box 659, Meadville, PA 16335. Attention: Hamfest Committee.

INDIANA: The Cass County Amateur Radio Club's second annual Hamfest, Sunday, May 6, from 7:00 AM to 4:00 PM, at the 4-H Fairgrounds. Rain or Shine. Go North to Logansport on Highway 25, turn right at road 100, follow signs. Advance tickets $1.50, $2.00 at gate. Outside setup free, undercover $1.00. Bring your own tables. Free overnight camping, plenty of refreshments. Talk on 146.517 and Logansport Repeater 147.78. Write to: K9DVI, Dave Rothermel, RR 4, Box 146 G, Logansport, IN 46947.

MICHIGAN: The Monroe County Radio Communications Association's annual Hamfest Swap and Shop, June 10, 8 AM to 4 PM. Monroe Community College, Raisinville Rd. off M-59. Donation $1.00 at gate. More Details? CHECK — OFF Page 118

May 1979 | Page 105
NEW JERSEY: The Raritan Valley Radio Club (WQWQ Group) 8th annual Hamfest and Flea Market, Saturday, June 16, 8:30 AM to 4:00 PM, Columbia Park, Dunellen. For info: Robert Szklarz, RD 3, Box 317, Somerset, N.J. 08867 or (201) 354-8583 (WB2MME).

NEW JERSEY: Tri County Radio Association, Inc. Flea Market will be held at the Passaic Township Youth Center, Spring Lake, on Sunday, May 27, 1979. For information, write the Association at P.O. Box 412, Spring Lake, New Jersey, 07762 or call W2CHA at (201) 647-3461.

NEW YORK: Rochester Hamfest, May 27-29, Monroe County Fairgrounds (Route 15A) Rochester. Registration $4.00. $1.00 parking permit good throughout Hamfest. Outdoor tables $6.00 each. Indoor deadline for ticket holders. Saturday and Sunday only starting at 7:00 AM. Outdoor starts at 1:00 PM. Scoring and closing Sunday at 5:00 PM. Tickets: Rochester Hamfest 737 Latta Rd., Rochester, N.Y. 14612.

NEW YORK: The Southern Tier Amateur Radio Club's (Binghamton) 13th annual Hamfest, May 26, at the Lutheran Fellowship Recreation Center, exit 71 N. on Stella (I-88) Road. General admission: $2.00, Banquet $7.00 (including general admission). Free flea market, parking, refreshments. Inside tables $5.00 each. Reservations only for ticket: B.S.T.A.R.C., P.O. Box 11, Endwell, N.Y. 13760.

WISCONSIN: The Milwaukee UHF Society's second annual Swapfest, Sunday, May 13, starting at 7:00 AM, Waukesha County Expo Center, Waukesha. Admission: $1.50 advance, 2.00 gate. Prizes, refreshments. For tickets: BASE, Swapfest, Box 49, North Prairie, WI 53153.

1979 WEST VIRGINIA QSO PARTY. All Amateur Radio operators are invited to participate in the 1979 West Virginia QSO Party. The party is sponsored by the West Virginia State Amateur Radio Club. The contest period runs from 2330Z, June 16, to 2330Z, June 17, and there are no time limits on operating. The contest rules are: 1. The same station may be worked on different bands for additional points. Only one contact of each station may be scored for scoring. 2. Stations making contact should exchange QSO number, signal report, and county (if in West Virginia) state, or country. 3. West Virginia stations may work each other. 4. Out-of-state stations determine their score by multiplying the number of eligible QSOs with West Virginia stations by the number of different states made contacts. This total should be multiplied by the multiplier power indicated in paragraph 6. 5. West Virginia stations determine their score by multiplying the number of eligible QSOs with the different states made contacts. This total should be multiplied by the multiplier power indicated in paragraph 6. If a multiplier power is not indicated in paragraph 6, a multiplier power of 50 will be as follows: DC input of 200 watts or less — 1.5, DC output of 200 watts to legal limit. 1.0. An award for an operator may be given to an unsanctioned operator. 8. Logs should be sent to: West Virginia QSO Party, P.O. Box 36, Seneca Rocks, West Virginia 26884.

THE MINNESOTA QSO PARTY, sponsored by the Heartland Amateur Radio Club, will be held June 16 to 17, 1979, from 0000Z, June 16 to 2330Z, June 17. 3. Only one transmitter is allowed in operation at any one time; no crossband. Novices may operate with other Novice class operators. 9. For further information contact HARC, c/o Scott Nelson, W2EZF, 421 West Wisconsin Avenue, St. Paul, MN 55107.

THE VKZL/LOCEANIA DX CONTEST 1979 will be held June 16 and 17, 1979, running from 1000 GMT Saturday to 1000 GMT Sunday. All Amateur Bands, 3.5 MHz through to 28 MHz, can be used for contacts. There are three classes: (a) Single operator, (b) Multi-operator, (c) SWL. Listeners must be logged by the stations operated must be logged by all operators together with a list of their calligns. Logs of SWL listeners must be signed by the stations operated. Incomplete logs are not eligible for scoring. Stations will send serial number which consists of 3.5K, I6, and 3.5MHz. Logs must be received by the Contest Committee by the 18th of August 1979. The address for logs is: Bill Storer, VKZLS, 5 Prince Charles Rd., FRENCHs FOREST, 2006, N.S.W. Australia.

DIGITAL READOUT

for your HAM II or III

Kit MM-1 includes key components necessary to make conversion described in article by K1DG, Ham Radio, January 1979, p. 56.

- AD 2020    10-turn pot 5K    $3.95
- F9374     10-turn pot 1K    $3.95

Allow three weeks for delivery. Send check or M.O. for $29.95.

SUNSET ELECTRONICS
44 SUNSET DRIVE
FRAMINGHAM, MA 01701

16-POLE R-4C SSB!

- Stainless Steel Radiator
- Heavy Nickel-Chrome Plated Brass Base and Fittings
- Mounts Come with 17 RG-58AU and PL-259 Connectors
- Compatible with Motorola TAD and TAE M Aufgapters
- Complete antenna assembly with trunk lid
- "R" indicates for "in" mounting

- BM-2700T — 27-MHz 3½ wave length or QRP requires 100 watts rating. Covers 10 meters or 0.5 dB. A great mobile antenna for converted CB rigs. 49' at lowest frequency and is approximately 45' when cut for 10 meters. Complete with trunk lid mounting assembly. $29.95
- BM-MATH — Extra whip (Cut for 27 MHz only and one for CB) $5.00
- BM-4G70 — Same assembly except for 47-MHz $29.95
- BM-5800T — 144-174 MHz, 1-Watt gain antenna. 200 watt rating. Complete $29.95
- BM-MATE or BM-MATE 22-40 matching coils (these wires with loops) allow same mounting assembly to be used on different bands $14.95

Note: Deduct $4.00 from "T" price for "M" assemblies

Introducing Kantronics' Field Day
Morse Code/teletype reader and code speed display:

Kantronics' Field Day Morse Code/teletype reader and code-speed display reads code signals right off the air. Its powerful microcomputer system picks out signals, computes their speed, and reads even sloppy copy up to 80 words per minute!

1. Flies through the air with the greatest of ease.

Field Day is simple to use. You plug it into your station receiver just as you would a set of headphones.

Code and teletype conversations are converted from dots and dashes to standard alphanumeric text. The text advances across 10 big half-inch displays, and lab tests show that even the fastest CW is easily readable.

Field Day displays incoming or outgoing code speeds for you at the touch of a button. An accurate code speed-sampling program shows the speed right on the front panel. Everything is enclosed in a single, lightweight package that's small enough to fit in with the rest of your station.

2. Pay a little, get a lot.

In addition to a highly superior code-reading program and unique "on-board" speed display, Field Day has the specifications that make it a truly great code reader.

3. C'mon, take a test drive.

Check with these Authorized Kantronics dealers for more information on the Field Day Morse Code/teletype reader and code-speed display:

CRYS TAL FILTERS

The Heart of Your Set
Get the BEST FOR LESS!

YAESU -- KENWOOD -- HEATH -- and now

FOX-TANG O continues to expand its quality line of 8-pole filters, made up entirely of specially treated, high-Q crystals. Custom-made for each set with ultimate rejection of out-of-band frequencies. These filters are unavailable from other sources. Only FOX-TANGO has ownership for this type of filter. We have found that for most serious DXers and manufacturers, who have tried our filters, there is no other source for them. A set could be provided with a sharp (250 Hz) and a standard (900 Hz) CW filter, and/or a narrow (1800 Hz) SSB in addition to the regularly supplied SSB filter — all switch selectable. This provides superior variable bandwidth selection without the need for buying an expensive new model to provide it. In these inflationary times, it is a sound economics to upgrade your present set. FOX-TANGO makes it easy — and relatively inexpensive. (Order with confidence satisfaction guaranteed on a money back basis. Incidentally our current line of filters will fit many other brands or home-brew rigs. Check the specifications or write us about custom-built units for most rigs. (COMMNG YF45S F250 -- 750 Hz CW for 755 35/C (order one for your Collins now for faster delivery.)

DIODE SWITCHING RODWAYS

DUAL (2 FILTER) TYPE FOR ALL YAESU AND KENWOOD LISTED. Specify make and model — $21.00 airmailed postpaid. SINGLE (1 FILTER) TYPE FOR FT/FR-101 ONLY — $12.00 airmailed postpaid.

(To avoid error due to similarity of some filter numbers, specify desired unit completely when ordering. Include make and model of set, filter number desired, and center frequency.)

D R A K E (R-4C)!

DRAKE R-4C FILTERS AND ACCESSORIES

Spectacularly improve the performance of this excellent time-tested receiver, popular worldwide with the most successful DXers and Contesters, by adding our highest quality 8-pole filters and accessories. Compare our specifications and prices with those of others and you'll buy FOX-TANGO!

YF566H R (GUF-1). Broad first IF Filter. Superior 8-pole type (Shape factor 1.5, ultimate rejection >100dB) includes original unit (Shape factor 4.7, ultimate rejection 65dB). Used in CW/SSB modes. Drop in replacement of original unit — only two soldered connections. Recommended for use in conjunction with GUF-2. With complete instructions. GUF-1 $85 ppd. Add $3 for overseas airmailed.

YF566H R (GUF-2). Narrow first IF Filter. (Shape factor as low as 2.0, ultimate rejection >100dB) Both GUF-1 and GUF-2 improve dynamic range, reduce intermod due to overloading of second mixer, reduce QRM, etc. GUF-2 includes a relay kit and all parts needed to provide automatic selection of GUF-1 or GUF-2 depending upon the position of the Mode Switch, thus retaining phone capabilities lost if GUF-2 (CW) is used alone. Complete step-by-step instructions simplify installation. GUF-2, including relays and parts: $90 ppd. Add $3 for overseas airmailed.

YF566H R (GUF-3). Sharp 125Hz 8 pole, second IF Filter. (Shape factor as low as 2.0, ultimate rejection >100dB.) Sharpest CW filter available. See Specs in Table. If you can't get it with this filter, you can't get it — period! Puts selectivity where it counts: in the AGC loop. Eliminates loss of RX gain due to QRM outside of passband, commonly noted with audio filters — yet works well with them. Simple installation; plugs into accessory socket on back of the set. $100 ppd. Add $3 for overseas airmailed.

GUO Product Detector Kit. All parts and instructions needed to convert the existing detector to a double-conversion relay detector and to provide better isolation between input and output. Overcomes distortion in audio output and AGC attack. Includes compact PCB with active BHE/SN16913, relay switch, and access components. Detailed instructions, diagrams and photographs simplify installation. GUO Kit $45 ppd. Add $3 for overseas airmailed.

See you at the Atlanta HamFestival, June 16, 17!

Apollo Products-Little Giant Trans Systems Tuner Kit — $122.50

Designed and engineered after "Apollo" — "Little Giant" 2500X-2, for an "engineered performance" Trans Systems Tuner and Adaptations of the Lew McCoy Transmatch, with power handling at the KW plus level!

Kit includes:
1. 200 pfd wide-spaced variable isolating capacitors. Tolerance: ±10% at 3000 volts
2. 200 pfd dual section parallel condenser insulated
3. Condenser insulated
4. Finger-grip pointer knobs 2" in diameter white indexed
5. Insulated shaft couplings 1/4" to 1/4"
6. SO-239 coax chasis connectors.
7. Tungsten or 50-300 ohm, or random wires
8. 1 heavy inductance for 10-15-20-30-40-80 meters
9. 6 pvc stand-offs, 4 for condensers
10. 3 metal stand-off screws on all metal screws
11. 1 HD switch for band switching 10 thru 80 meter coverage
12. 1 knob for antenna selection
13. 10 gauge 22" driven and 59" balanced feeders
14. 100 ohm open spaced ladder line: air dielectric
15. 1 wire diam, 0.049 wire diam, info only — not supplied.

May 1979
WHY WISH YOU'D BOUGHT ALPHA?

IS SOMETHING ELSE "JUST AS GOOD?"

New ALPHA owners often tell us, "I wish I'd saved my time and money and bought an ALPHA in the first place." Why not benefit from their experiences? Compare first!

TRY TO GET ANY OTHER MANUFACTURER TO TELL YOU - IN WRITING - THAT IT'S SAFE TO OPERATE HIS DESK TOP LINEAR AT A FULL D-C KILOWATT . . . SAY FOR 24 HOURS KEY-DOWN. OR, ASK HIM FOR A FULL YEAR WRITTEN WARRANTY. LOTS OF LUCK!

YOUR NEW ALPHA WILL HAPPILY AND COOLY RUN THAT KILOWATT KEY-DOWN . . . FOR 24 DAYS IF YOU WISH. AND YOU'LL BE PROTECTED BY ETO'S UNMATCHED WARRANTY FOR TWO YEARS. WE PUT IT IN WRITING ALL THE TIME. IT'S THE WAY WE BUILD AND WARRANT EVERY ALPHA!

The new ALPHA's are the best we've ever built. Nothing else even approaches an ALPHA's combination of power, convenience, quality, and owner protection. The ETO/ALPHA two year limited warranty offers you eight times as much protection as the industry-standard 90 day warranty.

The new ALPHA 374A adds NO-TUNE-UP operation to all the other traditional ALPHA qualities and capabilities. You can hop instantly from one HF band to another, with full maximum legal power and with little or no amplifier tune-up at all! (If new amateur bands are added, you can manually adjust your ALPHA to work them, too.)

In 1974 the original ALPHA 374 set a standard of high power convenience that has remained unmatched since. Despite its small size, not even one 374 owner ever burned out a power transformer. Impressive? The new 374A has an even huskier power supply. And it has ETO's ducted-air system with acoustically-isolated centrifugal blower to insure cool, whisper-quiet operation.

Before you get serious about any other brand of linear, compare its convenience and quality, its transformer heat, its cooling system efficiency and noise level - and its warranty - with the ALPHA's. Be sure to ask around about its reputation.

Call or write for detailed literature and thoroughly check out all the great new ALPHA's . . . so you don't make a mistake.

Two EIMAC 3-500Zs provide the punch in Kenwood's new amplifier.

Kenwood chooses EIMAC for trouble-free service.

The new heavy-duty Kenwood TL-922A linear amplifier provides 2 kW PEP input for SSB service and 1 kW input for CW, RTTY, and SSTV operation.

Kenwood chose two EIMAC 3-500Z high-mu triodes to do the job. With a total of 1000 watts anode dissipation, the two 3-500Zs coast along to provide trouble-free, long-life service.

For more information

Send for the EIMAC Quick Reference catalog covering the complete line of EIMAC products and for the 3-500Z Data Sheet. Learn why the important manufacturers of communication equipment choose EIMAC. Varian, EIMAC Division, 301 Industrial Way, San Carlos, California 94070. Telephone (415) 592-1221. Or contact any of the more than 30 Varian Electron Device Group Sales Offices throughout the world.

What's your pleasure?

DX chasing? Traffic nets? RTTY? Rag chewing? SSTV? The EIMAC 3-500Z provides the power when you need it, with ample safety margin. Value wise amateurs always look for the EIMAC power tube for reliability. And equipment manufacturers, such as Kenwood, choose EIMAC for leadership in power tube technology.
